Abstract

In the design of modern accelerators an accurate estimate of coupling impedance is very important. The sources which give rise to coupling impedance are the geometric discontinuities in the accelerator beam pipe. In various discontinuities such as RF cavities, bellows and collimators the coupling impedance of the holes has not been well understood. Although coupling impedance can be obtained in general from the Fourier transform of the corresponding wake potential which may be obtained numerically this is time consuming and requires a large amount of computer storage when applied to a small dimension of a discontinuity in a typical beam pipe often imposing a fundamental limitation of the numerical approach. It is especially true for the holes since the typical size of a hole is small compared with the dimension of a typical beam pipe. More fundamentally however numerical calculation does not have the predictive power because of limited understanding of how the coupling impedance of a hole should behave over a wide frequency range. This question was studied by developing a theoretical analysis based on a variational method.

An analytical formula for the coupling impedance of a hole is developed in this work using a variational method. The result gives good qualitative agreements with the coupling impedances evaluated numerically from the Fourier transform of the wake potential which is obtained from the computer code MAFIA-T3. We show that the coupling impedance of a hole behaves quite similar to the impedance of an RLC-resonator circuit. Important parameters used to describe such a resonator circuit are the resonant frequency and bandwidth. These parameters can be easily determined from the formula presented in this work. We provide a theoretical insight on how to parameterize properly the numerical impedance of a hole when data exhibit

complicated dependence on frequency. This is possible because we can show that the parameters are a function of the dimensionless quantity kd alone with k the free-space wave number and d the radius of hole.

In summary we will develop an analytical method for the hole-coupling problem valid for a wide range of frequencies.

Introduction

1.1 Introductory Remarks

In a circular accelerator a charged particle gains energy from the electromagnetic field in RF cavities. In electron storage rings RF power should compensate the synchrotron radiation loss experienced by the charged particle. While an accelerator is designed such that particles execute a stable longitudinal oscillation in the potential well provided by the RF system they should be stable in the transverse directions as well. For transverse motion the interaction is between the charged particle and the external magnetic field which provides the transverse focusing force. Since both RF fields and magnetic fields are supplied by the system external to particles the motion in such a field does not depend on the intensity of the beam. Hence we may call this type of motion single particle dynamics in contrast to a collective motion which is affected by the beam intensity also.

When an accelerator beam pipe is smooth everywhere single particle dynamics alone is sufficient in understanding the behavior of the beam inside an accelerator. In general however an accelerator beam pipe is not smooth but discontinuous in its dimension. An obvious discontinuity in a beam pipe is the RF cavities. Other

examples may include bellows, collimators, and pumping holes. Such unavoidable discontinuities in an accelerator beam pipe provide rich sources of interaction between the beam and the surroundings in such a way that when the beam traverses a discontinuity, say an RF cavity, the source field associated with the beam is scattered leaving the wake field behind the beam. The wake field then acts on the following bunch of particles or acts on the original beam itself. This self-sustained mechanism is continued either leading to a stable or to an unstable situation. Since the interaction depends on the intensity of beam, the dynamics of the system is often dominated by the so-called “collective effects.”

In modern accelerators or storage rings, the maximum achievable current is limited by the collective effects. In the equation of motion which characterizes the collective effects, the concept of wake potential and its frequency domain counterpart, coupling impedance, have been introduced, providing a coherent force in the equation of motion. Thus, in designing high-intensity accelerators and storage rings, one tries to minimize the collective effects by reducing the wake potential or the coupling impedance, and this is the subject of the present work.

1.2 Definition of Longitudinal Wake Potential and Coupling Impedance

In this section we introduce the definition of longitudinal wake potential and coupling impedance. Even though mathematically rigorous theorems can be found in the standard literature [7], we emphasize the heuristic concept evolved over many years in accelerator physics. Once the concept of longitudinal wake potential becomes clear, extension to the transverse wake potential is straightforward.

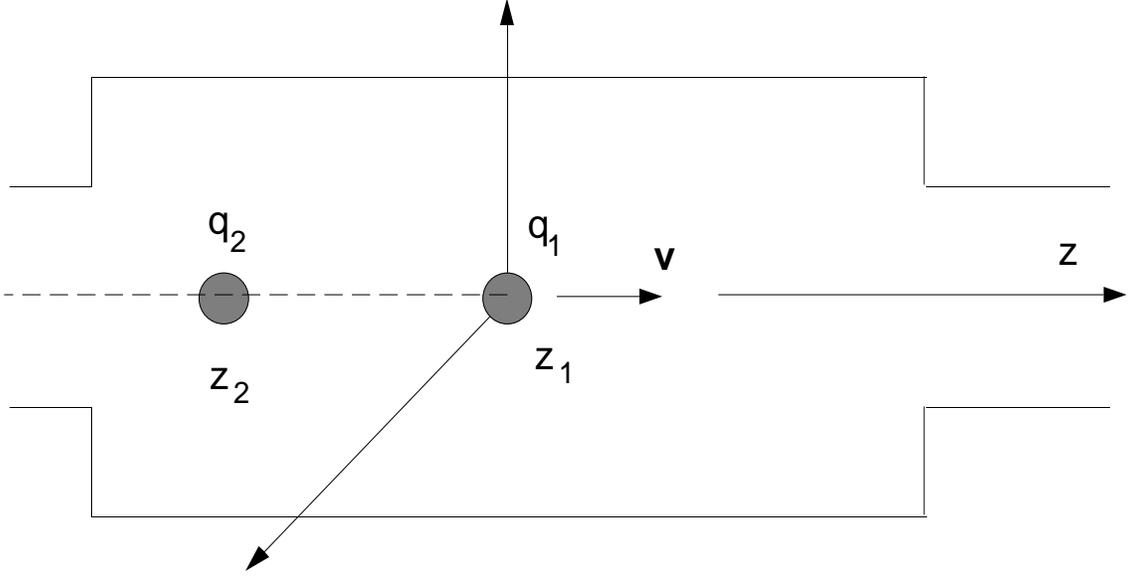

Figure 1.1: Leading (driving) and trailing (test) charges in a pill-box cavity with axial symmetry.

Let us consider two charges q_1 and q_2 traveling with constant velocity on the axis of an axially symmetric structure. At time $t = 0$ the position of leading charge is defined as $z_1 = 0$. At time t leading and trailing charges have coordinates $z_1(t) = vt$ and $z_2(t) = v(t - \tau)$ where τ is the time delay of the trailing charge (see Fig. 1.1).

Since the wake field excited by q_1 exerts the Lorentz force on the trailing charge the trailing charge experiences the energy change by an amount

$$\Delta U = -q_2 \int_{-\infty}^{\infty} E_z \left(z, t = \frac{z}{v} + \tau \right) dz, \quad (1.1)$$

where the electric field is computed at a later time and the unit is [Volt Coulomb].

We define the wake potential $W(\tau)$ as the energy lost by the trailing charge per unit of both charges q_1 and q_2 which can be expressed in the form

$$W(\tau) = \frac{\Delta U}{q_1 q_2} = -\frac{1}{q_1} \int_{-\infty}^{\infty} E_z \left(z, t = \frac{z}{v} + \tau \right) dz \quad (1.2)$$

with the unit of [Volt/Coulomb].

Once the response to a point driving charge q_1 is calculated the wake potential $W(\tau)$ can be used as Green's function to compute the potential in and behind an arbitrary charge distribution by means of the superposition principle. If the charge q_1 is continuously distributed according to the time distribution function $I(\tau)$ such that

$$q_1 = \int_{-\infty}^{\infty} I(\tau) d\tau, \quad (1.3)$$

the trailing charge experiences the effect due to a bunch distribution

$$V(\tau) = \int_{-\infty}^{\infty} W(\tau - \tau') I(\tau') d\tau' \quad (1.4)$$

with the unit of [Volt]. The potential in Eq. (1.4) is sometimes called bunch potential. Since bunch potential depends on the distribution of charges the wake potential is a more fundamental quantity as it depends only on the structure surrounding a charge.

If we take the Fourier transform of Eq. (1.4) we have a response relation in the frequency domain such that

$$Z(\omega) = W(\omega) = \frac{V(\omega)}{I(\omega)}, \quad (1.5)$$

where $W(\omega)$ is a Fourier transform of wake potential and is defined as

$$W(\omega) = \int_{-\infty}^{\infty} W(\tau) e^{-j\omega\tau} d\tau. \quad (1.6)$$

Since the quantity $Z(\omega)$ is the ratio of voltage and current it will be called *impedance* or *coupling impedance* with [Ohm] as its unit.

For the calculation of bunch potential general-purpose computer codes exist: TBCI [31] for axially symmetric geometries and MAFIA-T3 [17] for three-dimensional

geometries. Although direct numerical calculation of wake potential is impossible because of the finite size of the mesh used in these codes we can obtain the impedance via Eq. (1.5) from the discrete bunch potential. For the analytic calculation however it would be much easier to work directly in the frequency domain noting that

$$Z(k) = -\frac{1}{I_0} \int_{-\infty}^{\infty} E_z(z, k) e^{jkz} dz, \quad (1.7)$$

where $k = \omega/v$ is the wave number $I_0 = q_1 v$ is the dc current and the time dependence is assumed to be $\exp(j\omega t)$. This definition requires the field everywhere along the beam axis or along the gap if the structure is a cavity type. It should be noted also that the field integral in Eq. (1.7) is the effective voltage including the transit time factor experienced by the charge traversing RF cavity.

Since the drive current in the frequency domain has a sinusoidal dependence on z of the form

$$\mathbf{J}(x, y, z; k) = I_0 \delta(x) \delta(y) e^{-jkz} \mathbf{e}_z, \quad (1.8)$$

we can express Eq. (1.7) as

$$Z(k) = -\frac{1}{|I_0|^2} \int_{-\infty}^{\infty} \mathbf{E} \cdot \mathbf{J}^* dV. \quad (1.9)$$

In this form coupling impedance used in the accelerator physics is equal to the input impedance of the source which excites the waveguide or cavity.

It will be shown in the next section that Eq. (1.9) is more convenient for a certain geometry especially for a hole problem.

1.3 Aperture Problem and Gluckstern's Formalism

Maintaining a high vacuum in a storage ring is essential for a useful beam lifetime which is typically many hours. Since the residual gas must be pumped out of the beam pipe, pumping holes are distributed around the ring for the passage of residual gas. Although the arrangement of pumping holes is different in different accelerators, the impedance of even a single hole is not a well-known quantity.

Numerical calculation using computer codes for the wake potential is possible but it will be time consuming since

1. the geometry describing a beam pipe with holes is three dimensional
2. a large amount of computer storage will be required because the computation will need a fine mesh in order to resolve the 1 or 2 mm thickness of the hole-plate
3. it is always difficult to obtain the impedance in the high frequency range because errors in the Fourier transformation are amplified in the convolution defined in Eq (1.5).

Finding an analytic expression for the impedance of a hole in a broad frequency range is therefore highly desirable in the design of high intensity storage rings.

Among many different ways of calculating impedance, Gluckstern's formalism [10, 11, 12] is particularly useful and is introduced in this section. Let us consider two axially symmetric beam pipes, one without a hole and the other with a hole shown in Fig. 1.2. If we denote the field in the smooth beam pipe as $\mathbf{E}_1, \mathbf{H}_1$ which is the source field, and the field in the beam pipe with a hole as $\mathbf{E}_2, \mathbf{H}_2$ which is the

source field plus scattered field due to a hole. They satisfy Maxwell's equations in the form

$$\nabla \times \mathbf{E}_{1,2} = -j\omega\mu\mathbf{H}_{1,2}, \quad \nabla \times \mathbf{H}_{1,2} = j\omega\epsilon\mathbf{E}_{1,2} + \mathbf{J}, \quad (1.10)$$

where $\mathbf{J} = I_0\delta(x)\delta(y)e^{-jkz}\mathbf{e}_z$ is the complex current density and $k = \omega\sqrt{\epsilon_0\mu_0}$ is the free-space wave number. Assuming that the velocity of traveling charge is ultrarelativistic ($\beta = v/c \simeq 1$, $\gamma = 1/\sqrt{1-\beta^2} \gg 1$ which is assumed throughout) and using a well-known result of the impedance due to the source field

$$Z_1(k) = -\text{constant} \times \frac{j}{\gamma^2}, \quad (1.11)$$

we can construct

$$|I_0|^2[Z_2(k) + Z_1^*(k)] = |I_0|^2[Z_2(k) - Z_1(k)] = -\int[\mathbf{E}_2 \cdot \mathbf{J}^* + \mathbf{E}_1^* \cdot \mathbf{J}]dV. \quad (1.12)$$

Noting the identity $\nabla \cdot (\mathbf{E}_1^* \times \mathbf{H}_2 + \mathbf{E}_2 \times \mathbf{H}_1^*) = -(\mathbf{E}_2 \cdot \mathbf{J}^* + \mathbf{E}_1^* \cdot \mathbf{J})$ we convert the volume integral into the surface integral leading to

$$|I_0|^2 Z_2(k) = \int \mathbf{n} \cdot [\mathbf{E}_2 \times \mathbf{H}_1^* + \mathbf{E}_1^* \times \mathbf{H}_2] dS, \quad (1.13)$$

where we used the fact that $Z_1(k)$ vanishes in the ultrarelativistic limit. If we choose S to be the inside surface of the beam pipe $\mathbf{n} \cdot \mathbf{E}_1^* \times \mathbf{H}_2 = 0$ we have

$$|I_0|^2 Z_2(k) = \int_{hole} (\mathbf{n} \times \mathbf{E}_2) \cdot \mathbf{H}_1^*, \quad (1.14)$$

where $\mathbf{n} \times \mathbf{E}_2$ is the tangential field inside the hole, a quantity unknown until we solve the problem completely.

Determining the field inside hole has been an important subject of investigation for a long time. Several hundred papers have been published on this subject and

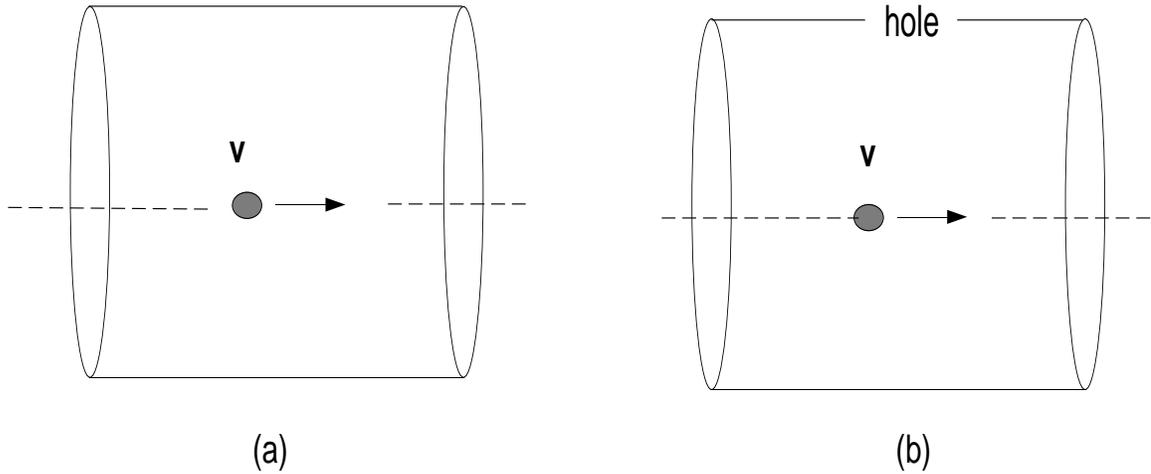

Figure 1.2: (a) A charge traveling in the smooth beam pipe (b) a charge traveling in the beam pipe with a hole.

an excellent review paper was written by Bouwkamp in 1954 [4]. Among the large amount of literature available Schelkunoff's *Field Equivalence Theorems* [26] Levine and Schwinger's variational formalism using dyadic Green's function [21] and Rumsey's *Reaction Concept* [23] are particularly useful for our problem. These works are summarized in Chapter 2.

1.4 Goal and Scope of the Work

Obtaining an analytical estimate of longitudinal coupling impedance of a hole is the main goal of this work. Since the exact solution is hard to obtain we try to find an approximate solution based on a variational principle. This approximate solution should be valid in a wide frequency range.

As mentioned in the previous section a hole cut in the surface imposes a fundamental problem in vector diffraction theory. Relevant theorems and formalism for our impedance problem are summarized in Chapter 2. In Chapter 3 the most important

in the dissertation we apply diffraction theorems to a particularly simple geometry namely a hole in an infinitely flat screen. Although accelerator beam pipe is torus in shape with circular elliptical or rectangular cross section we consider the beam pipe with rectangular cross section because other shapes raise the question of curvature effect of a hole which is not essential to our problem. Analytic results and comparison with numerical estimates are presented in Chapter 4. Conclusions and suggestions for a further investigation are presented in Chapter 5.

Chapter 2

Vector Diffraction Theory

2.1 Introduction

The diffraction problem deals with the interaction between waves of finite wavelengths and obstacles. A geometric theory describing the diffraction pattern was developed by Huygens and Fresnel whose idea was put forward in the mathematical form by Kirchhoff. Kirchhoff's scalar diffraction theory is based on the integral equation whose solution is in general impossible to find Γ and hence subject to the various approximations for solutions. When Kirchhoff applied his formula to the problem of diffraction by the black (or opaque) screen with an aperture in it Γ he assumed that [16]:

1. A field function (ψ) and its normal derivative ($\frac{\partial\psi}{\partial n}$) on the screen vanish except in the aperture.
2. The values of ψ and $\frac{\partial\psi}{\partial n}$ in the aperture are equal to the values of the incident waves in the absence of any screen or obstacles.

It is these approximations that contain mathematical inconsistencies and physical deficiencies and not the Kirchhoff integral equation itself [2].

Since Kirchhoff's integral equation is based on the scalar Green's function it does not satisfy Maxwell's equations in general. A vector analog of Kirchhoff's integral equation was developed by Stratton and Chu [27] which requires not only the tangential electric and magnetic fields but also the normal electric fields on the entire boundary surface surrounding the region of interest where the fields are to be computed. The choice of vector Green's function is rather arbitrary. The proper choice of Green's function will remove the normal electric fields from the integral equation [22].

Green's function Γ which relates the vector fields and the vector sources Γ should be in general dyadic or tensor quantity. In particular Γ when we want to compute the fields directly by solving vector wave equations for fields instead of resorting to the use of vector potential Γ the dyadic Green's function has a considerable advantage over a vector Green's function in simplifying the notation. Levine and Schwinger [21] used the dyadic notation on the theory of electromagnetic wave diffraction by an aperture in an infinite plane conducting screen. Employing variational principles Γ they calculated the transmission coefficient with a great accuracy comparable to the rigorous solution obtained by solving partial differential equations analytically. This is the motivation for using the dyadic Green's function throughout our work.

In Section 2.2 Γ we explain the field equivalence principle which is helpful in understanding the physics involved in the diffraction phenomena. The brief introduction of dyadic Green's function which will be used later is laid out in Sections 2.3 and 2.4. The field equivalence principle will emerge as a natural part of the theory of dyadic Green's function. In Section 2.5 Γ we introduce the Rumsey's reaction concept which not only simplifies the notation but also proves to be useful in deriving the

variational formula for various quantities of interest. In Section 2.6 we calculate the transmission coefficient of a plane wave incident on the infinite plane with an aperture using all the concepts and formalisms laid out in the previous sections.

2.2 Field Equivalence Principle

Various field equivalence principles provide different ways of formulating a boundary-value problem [9, 14, 24, 25, 26]. As an example consider a solution of Poisson's equation in electrostatic problems. The region V surrounded by the surface S contains no charge. Applying Green's theorem one can determine uniquely the potential in the region V due to the charge distribution external to S by specifying a surface charge and a dipole layer density on the surface S . This illustrates one form of equivalence principle for we replaced the original volume source with the equivalent surface sources on the mathematical boundary.

A simple application of the equivalence principle for the time-varying electromagnetic fields is illustrated in Fig. 2.1. The sources for an electromagnetic field are contained in a volume V_1 bounded by a smooth closed surface S as shown in Fig. 2.1a. Suppose we only need to evaluate the fields in the region V bounded by both the surface S and the surface at infinity S_∞ . For this purpose assume the original field in V and the null field in V_1 as shown in Fig. 2.1b. Since the fields change discontinuously across S in Fig. 2.1b there must exist surface currents to satisfy the boundary conditions:

$$\mathbf{J} = \mathbf{H} \times \mathbf{n}, \quad \mathbf{J}_m = \mathbf{n} \times \mathbf{E},$$

where \mathbf{J} and \mathbf{J}_m denote the electric and magnetic currents respectively and \mathbf{n} is the unit vector outwardly normal from the region where the fields are to be calculated.

(This convention is used for the direction of unit normal vector throughout this work.) The integrated effect of these surface currents will uniquely determine the field in the region V . This is called *Love's field equivalence principle*. Evidently this does not make the problem any easier to solve since we do not know the equivalent surface currents until the problem is solved. Since we know that the field can be uniquely determined by the tangential components of \mathbf{E} -field or \mathbf{H} -field on the surface alone [28] we may modify Love's field equivalence principle such that it requires only magnetic (tangential \mathbf{E}) or electric currents (tangential \mathbf{H}).

Since the field in the region V_1 is zero we may place a perfect electric conductor over S without affecting the field in V_1 . Over this conducting surface we have equivalent current source \mathbf{J} and \mathbf{J}_m . The tangential \mathbf{E} -field reduces to zero on the conductor surface which crosses the magnetic current sheet and the insertion of conductor does not affect the field in the region V due to \mathbf{J}_m . It can be shown also that an electric current just in front of an electric conductor produces a null field [9]. The field in the region V is then uniquely determined by the magnetic surface current (tangential \mathbf{E}) adjacent to the perfect electric conductor whose surface coincides with the S . In Green's function technique this is equivalent to finding Green's function to satisfy the boundary conditions for the perfect electric conductor. Similarly if we place the perfect magnetic conductor on S we only need the electric surface currents (tangential \mathbf{H}) to determine the field uniquely in the region V . This modification to Love's field equivalence principle is called *Schelkunoff's field equivalence principle* and is illustrated in Fig. 2.2.

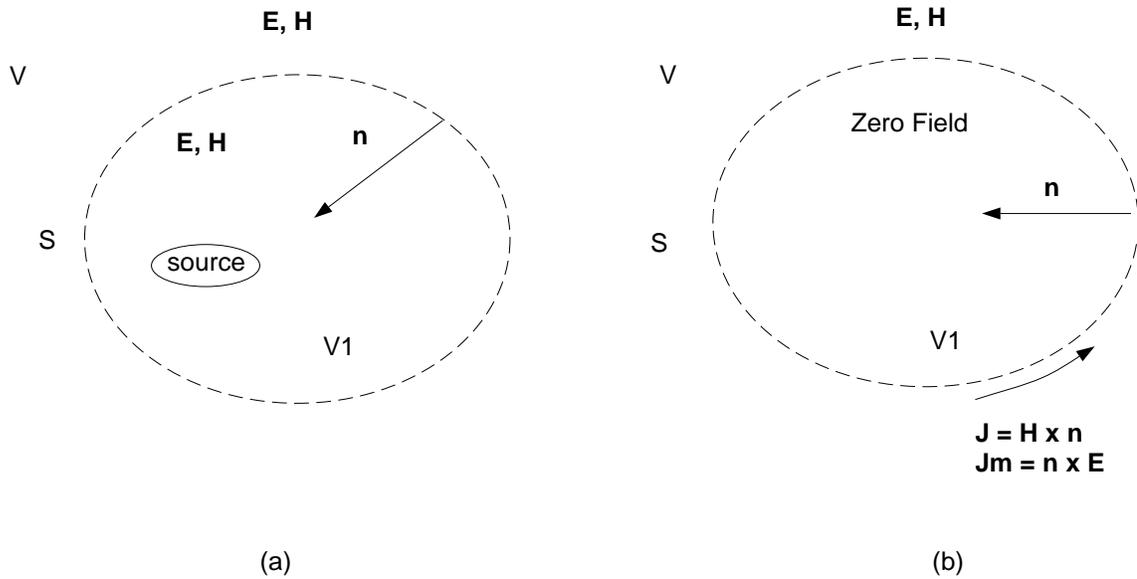

Figure 2.1: Illustration of Love's field equivalence principle. (a) Original problem; (b) equivalent to (a).

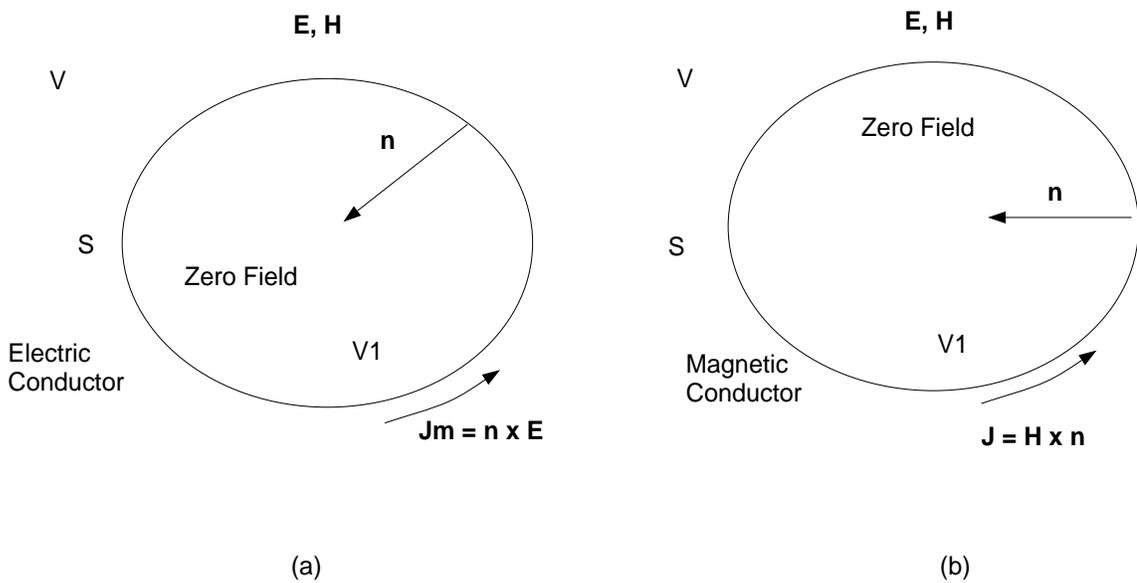

Figure 2.2: Illustration of Schelkunoff's field equivalence principle. (a) magnetic current over electric conductor; (b) electric current over magnetic conductor.

2.3 Free-Space Dyadic Green's Function

Maxwell's equations in the phasor form are

$$\nabla \times \mathbf{E} + j\omega\mu\mathbf{H} = -\mathbf{J}_m, \quad (2.1)$$

$$\nabla \times \mathbf{H} - j\omega\epsilon\mathbf{E} = \mathbf{J}, \quad (2.2)$$

$$\nabla \cdot \mathbf{H} = \rho_m/\mu, \quad (2.3)$$

$$\nabla \cdot \mathbf{E} = \rho/\epsilon. \quad (2.4)$$

It is assumed that all quantities vary as $e^{j\omega t}$. Quantities \mathbf{J}_m and ρ_m are densities of magnetic current and magnetic charge respectively. Currents and charges are related by the equation of continuity

$$\nabla \cdot \mathbf{J} + j\omega\rho = 0, \quad (2.5)$$

$$\nabla \cdot \mathbf{J}_m + j\omega\rho_m = 0. \quad (2.6)$$

The vector wave equation for \mathbf{E} is obtained by taking curl of curl \mathbf{E} resulting in

$$\nabla \times \nabla \times \mathbf{E} - k^2\mathbf{E} = -j\omega\mu\mathbf{J} - \nabla \times \mathbf{J}_m, \quad (2.7)$$

where $k^2 = \omega^2\mu\epsilon$. In a similar fashion we find that \mathbf{H} is a solution of

$$\nabla \times \nabla \times \mathbf{H} - k^2\mathbf{H} = -j\omega\epsilon\mathbf{J}_m + \nabla \times \mathbf{J}. \quad (2.8)$$

We can derive either Eq. (2.7) or (2.8) from the other using the substitutions $\mathbf{E} \rightarrow \mathbf{H}\Gamma$, $\mathbf{H} \rightarrow -\mathbf{E}\Gamma$, $\mathbf{J} \rightarrow \mathbf{J}_m\Gamma$, $\mathbf{J}_m \rightarrow -\mathbf{J}\Gamma$ and $\epsilon \leftrightarrow \mu$.

Both \mathbf{E} and \mathbf{H} fields satisfy the linear vector equation in the form

$$\mathcal{L}\mathbf{f} = \mathbf{g}. \quad (2.9)$$

We first note that in general the solution cannot be expressed in terms of a single scalar Green's function as for example

$$\mathbf{f}(\mathbf{r}) = \int_V G(\mathbf{r}|\mathbf{r}')\mathbf{g}(\mathbf{r}')dV'.$$

Such a relationship implies that the source $\mathbf{g}(\mathbf{r}')$ everywhere parallel to the x axis generates field $\mathbf{f}(\mathbf{r})$ parallel to the same axis. This is true for the relationship between the current source and the magnetic vector potential but not for the fields. It is therefore necessary to use nine scalar Green's functions to express the three components of $\mathbf{f}(\mathbf{r})$ in terms of three components of the source $\mathbf{g}(\mathbf{r}')$. One of such nine scalar Green's functions $G_{xy}(\mathbf{r}|\mathbf{r}')$ measures the x -component of the field at \mathbf{r} due to a unit y -directed source at \mathbf{r}' .

Thus the equations for $\mathbf{f}(\mathbf{r})$ can be written as [6]

$$\mathbf{f}(\mathbf{r}) = \int (\mathbf{G}_x \mathbf{e}_x \cdot \mathbf{g} + \mathbf{G}_y \mathbf{e}_y \cdot \mathbf{g} + \mathbf{G}_z \mathbf{e}_z \cdot \mathbf{g}) dV' = \int \overline{\mathbf{G}} \cdot \mathbf{g} dV', \quad (2.10)$$

where $\overline{\mathbf{G}}$ is the dyadic Green's function defined as

$$\overline{\mathbf{G}} = \mathbf{G}_x \mathbf{e}_x + \mathbf{G}_y \mathbf{e}_y + \mathbf{G}_z \mathbf{e}_z. \quad (2.11)$$

(In this work bold characters are used to denote vectors and bold characters with a bar to denote dyadic quantities.) The \mathbf{G} 's are the column vector of the dyadic Green's function $\overline{\mathbf{G}}$ for example as

$$\mathbf{G}_x = G_{xx} \mathbf{e}_x + G_{yx} \mathbf{e}_y + G_{zx} \mathbf{e}_z. \quad (2.12)$$

In the matrix notation Eq. (2.10) may be rewritten as

$$\begin{bmatrix} df_x \\ df_y \\ df_z \end{bmatrix} = \begin{bmatrix} G_{xx} & G_{xy} & G_{xz} \\ G_{yx} & G_{yy} & G_{yz} \\ G_{zx} & G_{zy} & G_{zz} \end{bmatrix} \begin{bmatrix} dg_x \\ dg_y \\ dg_z \end{bmatrix}, \quad (2.13)$$

or in the tensor notation

$$f_i = \int G_{ij} g_j dV'. \quad (2.14)$$

Consider the vector wave equation for \mathbf{E} in the free space excited by the electric current

$$\nabla \times \nabla \times \mathbf{E} - k^2 \mathbf{E} = -j\omega\mu\mathbf{J}. \quad (2.15)$$

The dyadic Green's function of electric type is defined as a solution of

$$\nabla \times \nabla \times \overline{\mathbf{G}}_e - k^2 \overline{\mathbf{G}}_e = \overline{\mathbf{I}}\delta(\mathbf{r} - \mathbf{r}'), \quad (2.16)$$

where $\overline{\mathbf{I}}$ is the unit dyadic defined as

$$\overline{\mathbf{I}} = \mathbf{e}_x \mathbf{e}_x + \mathbf{e}_y \mathbf{e}_y + \mathbf{e}_z \mathbf{e}_z. \quad (2.17)$$

Subscript e of $\overline{\mathbf{G}}_e$ denotes the Green's function of electric type. We do not impose any boundary conditions on $\overline{\mathbf{G}}_e$ except that it should satisfy the radiation condition at infinity.

Following Levine and Schwinger [21] we transform Eq. (2.16) to the vector Helmholtz wave equation form. A vector identity

$$\nabla \times \nabla \times = \nabla \nabla \cdot - \nabla^2,$$

can be used to obtain

$$(\nabla^2 + k^2)\overline{\mathbf{G}}_e(\mathbf{r}|\mathbf{r}') = -(\overline{\mathbf{I}} + \frac{1}{k^2}\nabla\nabla)\delta(\mathbf{r} - \mathbf{r}'). \quad (2.18)$$

Since we know that in free space the scalar Green's function $G(\mathbf{r}|\mathbf{r}')$ obeys the relation

$$(\nabla^2 + k^2)G(\mathbf{r}|\mathbf{r}') = -\delta(\mathbf{r} - \mathbf{r}'), \quad (2.19)$$

the corresponding dyadic Green's function should be in the form

$$\overline{\mathbf{G}}_e(\mathbf{r}|\mathbf{r}') = (\overline{\mathbf{I}} + \frac{1}{k^2}\nabla\nabla)G. \quad (2.20)$$

The scalar Green's function satisfying the radiation condition is well known as

$$G(\mathbf{r}|\mathbf{r}') = G(R) = \frac{e^{-jkR}}{4\pi R}, \quad (2.21)$$

where $R = |\mathbf{R}| = |\mathbf{r} - \mathbf{r}'|$ is the distance between the source point \mathbf{r}' and the field point \mathbf{r} . Thus the dyadic Green's function is

$$\overline{\mathbf{G}}_e(\mathbf{r}|\mathbf{r}') = (\overline{\mathbf{I}} + \frac{1}{k^2}\nabla\nabla)\frac{e^{-jkR}}{4\pi R}. \quad (2.22)$$

The hierarchy of the above dyadic Green's function becomes clear by constructing an explicit coordinate-free form [8]. In order to do that we will use the following relationships

$$\nabla R = \hat{\mathbf{R}} \quad (2.23)$$

$$\nabla\hat{\mathbf{R}} = \frac{1}{R}(\overline{\mathbf{I}} - \hat{\mathbf{R}}\hat{\mathbf{R}}), \quad (2.24)$$

where $\mathbf{R} = \mathbf{r} - \mathbf{r}'$ and $\hat{\mathbf{R}} = \mathbf{R}/R$.

Using the chain rule that if $f(u)$ is a function of u and u is a function of \mathbf{r} we have

$$\nabla f = \frac{df}{du}\nabla u.$$

With the aid of the above relations we obtain

$$\nabla\frac{e^{-jkR}}{R} = -\left(jk + \frac{1}{R}\right)\frac{e^{-jkR}}{R}\hat{\mathbf{R}}, \quad (2.25)$$

and

$$\nabla\nabla\frac{e^{-jkR}}{R} = \left[-\left(\frac{jk}{R} + \frac{2}{R^2}\right)(\overline{\mathbf{I}} - 3\hat{\mathbf{R}}\hat{\mathbf{R}}) - k^2\hat{\mathbf{R}}\hat{\mathbf{R}}\right]\frac{e^{-jkR}}{R}. \quad (2.26)$$

Substituting Eq. (2.26) into Eq. (2.22) we finally obtain

$$\overline{\mathbf{G}}_e(\mathbf{r}|\mathbf{r}') = (\overline{\mathbf{I}} - \hat{\mathbf{R}}\hat{\mathbf{R}})G(R) - \frac{j}{kR}(\overline{\mathbf{I}} - 3\hat{\mathbf{R}}\hat{\mathbf{R}})G(R) - \frac{1}{k^2R^2}(\overline{\mathbf{I}} - 3\hat{\mathbf{R}}\hat{\mathbf{R}})G(R). \quad (2.27)$$

The first term which varies as $1/R$ is the *radiation term* which is purely transverse to the direction \mathbf{R} as the dyad $\overline{\mathbf{I}} - \hat{\mathbf{R}}\hat{\mathbf{R}}$ projects any vector perpendicular to $\hat{\mathbf{R}}$. Thus the radiation field far from the source is a plane wave. The second and third terms are also familiar *induction* and *electrostatic terms* respectively. For an arbitrary current distribution the electric field will be

$$\mathbf{E}(\mathbf{r}) = -j\omega\mu \int \overline{\mathbf{G}}_e(\mathbf{r}|\mathbf{r}') \cdot \mathbf{J}(\mathbf{r}') dV'. \quad (2.28)$$

Similarly for \mathbf{H} fields due to the magnetic currents satisfying

$$\nabla \times \nabla \times \mathbf{H} - k^2\mathbf{H} = -j\omega\epsilon\mathbf{J}_m, \quad (2.29)$$

the dyadic Green's function of magnetic type is defined as the solution of

$$\nabla \times \nabla \times \overline{\mathbf{G}}_m - k^2\overline{\mathbf{G}}_m = \overline{\mathbf{I}}\delta(\mathbf{r} - \mathbf{r}'). \quad (2.30)$$

For an arbitrary magnetic current distribution the magnetic field will be

$$\mathbf{H}(\mathbf{r}) = -j\omega\epsilon \int \overline{\mathbf{G}}_m(\mathbf{r}|\mathbf{r}') \cdot \mathbf{J}_m(\mathbf{r}') dV'. \quad (2.31)$$

$\overline{\mathbf{G}}_m$ is obviously equal to $\overline{\mathbf{G}}_e$ and we denote both as $\overline{\mathbf{G}}_0$ which is called the *free-space dyadic Green's function*. In general the dyadic Green's functions of electric type and magnetic type are different from each other when the explicit boundary conditions are included in the definition of Green's function. For example in the region bounded by a perfectly conducting wall the boundary conditions on the surface satisfied by the Green's function are such that

$$\mathbf{n} \times \overline{\mathbf{G}}_e = 0, \quad \mathbf{n} \times \nabla \times \overline{\mathbf{G}}_m = 0, \quad (2.32)$$

which says that the tangential electric field on the electric conductor vanishes. Thus $\overline{\mathbf{G}}_e \neq \overline{\mathbf{G}}_m$ in general.

From Eq. (2.27) we see that the free-space dyadic Green's function has symmetrical properties

$$\overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') = \overline{\mathbf{G}}_0^T(\mathbf{r}'|\mathbf{r}), \quad \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') = \overline{\mathbf{G}}_0(\mathbf{r}'|\mathbf{r}), \quad (2.33)$$

where superscript T denotes the transpose of a dyadic. The first identity (often called *reciprocity relation*) is satisfied by all types of Green's function but the second one is special to the free-space case. These are useful because we can write

$$\overline{\mathbf{G}}_0 \cdot \mathbf{J} = \mathbf{J} \cdot \overline{\mathbf{G}}_0 \quad (2.34)$$

without worrying about ordering of the multiplication (i.e. $\overline{\mathbf{G}}_0$ commutes with an arbitrary vector).

2.4 Dyadic Green's Function and Field Equivalence Principle

Consider the source in the region V_1 shown in Fig. 2.1a bounded by the surface S . The fields of physical interest are those contained within the regions devoid of charges and currents. Such a region is denoted as V in Fig. 2.1a bounded by S and the surface at infinity S_∞ . The unit vector \mathbf{n} is normal to S outward from the region V . Then the electric field in V satisfies the source-free wave equation

$$\nabla \times \nabla \times \mathbf{E} - k^2 \mathbf{E} = 0. \quad (2.35)$$

We define the dyadic Green's function as a solution of

$$\nabla \times \nabla \times \overline{\mathbf{G}} - k^2 \overline{\mathbf{G}} = \overline{\mathbf{I}} \delta(\mathbf{r} - \mathbf{r}'). \quad (2.36)$$

This Green's function is defined in the unbounded space $V + V_1$ and it should satisfy the radiation condition. This is essentially the free-space dyadic Green's function previously denoted as $\overline{\mathbf{G}}_0$ but since we will impose a boundary condition later we will leave it as $\overline{\mathbf{G}}$.

In order to relate the field in V with the surface integral over S we use the Green's second vector identity written as

$$\int_{S+S_\infty} dS \mathbf{n} \cdot [\mathbf{B} \times (\nabla \times \mathbf{A}) - \mathbf{A} \times (\nabla \times \mathbf{B})] = \int_V dV [\mathbf{A} \cdot \nabla \times (\nabla \times \mathbf{B}) - \mathbf{B} \cdot \nabla \times (\nabla \times \mathbf{A})]. \quad (2.37)$$

Substituting $\mathbf{A}(\mathbf{r}') = \mathbf{E}(\mathbf{r}')$ and $\mathbf{B}(\mathbf{r}') = \overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) \cdot \mathbf{e}$ where \mathbf{e} is an arbitrary constant vector we obtain

$$\begin{aligned} & \int_{S+S_\infty} dS' \mathbf{n} \cdot [(\overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) \cdot \mathbf{e}) \times (\nabla' \times \mathbf{E}(\mathbf{r}')) - \mathbf{E}(\mathbf{r}') \times (\nabla' \times \overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) \cdot \mathbf{e})] \\ &= \int_V dV' [\mathbf{E}(\mathbf{r}') \cdot \nabla' \times \nabla' \times (\overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) \cdot \mathbf{e}) - (\overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) \cdot \mathbf{e}) \cdot \nabla' \times \nabla' \times \mathbf{E}(\mathbf{r}')]. \end{aligned} \quad (2.38)$$

Using the relation $\nabla \times \mathbf{E} = -j\omega\mu\mathbf{H}$ and noting that the surface integral vanishes on S_∞ we obtain

$$j\omega\mu \int_S dS' (\mathbf{n} \times \mathbf{H}) \cdot \overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) - \int_S dS' (\mathbf{n} \times \mathbf{E}) \cdot \nabla' \times \overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) = \begin{cases} \mathbf{E}(\mathbf{r}) & \text{if } \mathbf{r} \in V \\ 0 & \text{otherwise} \end{cases}, \quad (2.39)$$

where we used Eq. (2.35) and Eq. (2.36) to evaluate the volume integral. Physical interpretation of this will be made clearer by applying the relation [21, 29]

$$\nabla \times \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') = [\nabla' \times \overline{\mathbf{G}}_0(\mathbf{r}'|\mathbf{r})]^T \quad (2.40)$$

to see that

$$\begin{aligned} \mathbf{E}(\mathbf{r}) &= -j\omega\mu \int_S \overline{\mathbf{G}}(\mathbf{r}|\mathbf{r}') \cdot (\mathbf{H} \times \mathbf{n}) dS' - \nabla \times \int_S \overline{\mathbf{G}}(\mathbf{r}|\mathbf{r}') \cdot (\mathbf{n} \times \mathbf{E}) dS' \\ &= \mathbf{E} \text{ (due to } \mathbf{J} = \mathbf{H} \times \mathbf{n}) + \mathbf{E} \text{ (due to } \mathbf{J}_m = \mathbf{n} \times \mathbf{E}) . \end{aligned} \quad (2.41)$$

Thus we have proved Love's field equivalence principle. A corresponding expression for the magnetic field may be obtained by substituting $\mathbf{A}(\mathbf{r}') = \mathbf{H}(\mathbf{r}')$ and $\mathbf{B}(\mathbf{r}') = \overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) \cdot \mathbf{e}$ into Eq. (2.37) and the result is

$$-j\omega\epsilon \int_S dS' (\mathbf{n} \times \mathbf{E}) \cdot \overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) - \int_S dS' (\mathbf{n} \times \mathbf{H}) \cdot \nabla' \times \overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r}) = \begin{cases} \mathbf{H}(\mathbf{r}) & \text{if } \mathbf{r} \in V \\ 0 & \text{otherwise} \end{cases} \quad (2.42)$$

which is equivalent to replacing $\mathbf{E} \rightarrow \mathbf{H}\Gamma\mathbf{H} \rightarrow -\mathbf{E}\Gamma$ and $\mu \rightarrow \epsilon$ in Eq. (2.39).

If the surface S is a perfectly conducting wall Γ it will be convenient to distinguish electric and magnetic Green's functions $\overline{\mathbf{G}}_e$ and $\overline{\mathbf{G}}_m$ which satisfy the boundary conditions

$$\mathbf{n} \times \overline{\mathbf{G}}_e = 0, \quad \mathbf{n} \times \nabla \times \overline{\mathbf{G}}_m = 0. \quad (2.43)$$

The expression for the electric field can be obtained by replacing $\overline{\mathbf{G}}$ with $\overline{\mathbf{G}}_e$ in Eq. (2.39) Γ then the first integral vanishes because of the boundary condition. Similarly the magnetic field can be obtained by replacing $\overline{\mathbf{G}}$ with $\overline{\mathbf{G}}_m$ in Eq. (2.42) Γ then the second integral vanishes. The resulting expressions are

$$\mathbf{E}(\mathbf{r}) = - \int_S dS' (\mathbf{n} \times \mathbf{E}) \cdot \nabla' \times \overline{\mathbf{G}}_e(\mathbf{r}'|\mathbf{r}), \quad (2.44)$$

$$\mathbf{H}(\mathbf{r}) = -j\omega\epsilon \int_S dS' (\mathbf{n} \times \mathbf{E}) \cdot \overline{\mathbf{G}}_m(\mathbf{r}'|\mathbf{r}). \quad (2.45)$$

Using the symmetrical relations Eq. (2.50) and Eq. (2.53) below Γ we rewrite the above equations as

$$\mathbf{E}(\mathbf{r}) = -\nabla \times \int_S dS' \overline{\mathbf{G}}_m(\mathbf{r}|\mathbf{r}') \cdot (\mathbf{n} \times \mathbf{E}), \quad (2.46)$$

$$\mathbf{H}(\mathbf{r}) = -j\omega\epsilon \int_S dS' \overline{\mathbf{G}}_m(\mathbf{r}|\mathbf{r}') \cdot (\mathbf{n} \times \mathbf{E}), \quad (2.47)$$

which clearly show that the fields are due to the magnetic surface current. We have derived a mathematical expression of the Schelkunoff's field equivalence principle

shown in Fig. 2.2a. The other one corresponding to Fig. 2.2b will also be verified by interchanging the roles of $\overline{\mathbf{G}}_e$ and $\overline{\mathbf{G}}_m$.

Finally we summarize the useful symmetrical relations of dyadic Green's functions. The proof is given in Ref. [21].

$$\nabla \times \nabla \times \overline{\mathbf{G}} - k^2 \overline{\mathbf{G}} = \overline{\mathbf{I}} \delta(\mathbf{r} - \mathbf{r}'), \quad (2.48)$$

$$\mathbf{n} \times \overline{\mathbf{G}}_1 = 0, \quad \mathbf{n} \times \nabla \times \overline{\mathbf{G}}_2 = 0, \quad \mathbf{r} \text{ on } S, \quad (2.49)$$

$$\overline{\mathbf{G}}(\mathbf{r}|\mathbf{r}') = [\overline{\mathbf{G}}(\mathbf{r}'|\mathbf{r})]^T, \quad (2.50)$$

$$\nabla \times \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') = [\nabla' \times \overline{\mathbf{G}}_0(\mathbf{r}'|\mathbf{r})]^T, \quad (2.51)$$

$$\nabla \times \overline{\mathbf{G}}_1(\mathbf{r}|\mathbf{r}') = [\nabla' \times \overline{\mathbf{G}}_2(\mathbf{r}'|\mathbf{r})]^T, \quad (2.52)$$

$$\nabla \times \overline{\mathbf{G}}_2(\mathbf{r}|\mathbf{r}') = [\nabla' \times \overline{\mathbf{G}}_1(\mathbf{r}'|\mathbf{r})]^T. \quad (2.53)$$

2.5 Reaction Concept and Variational Formalism

Let \mathbf{E}^a and \mathbf{H}^a be the fields in volume V bounded by a closed surface S and excited by volume distribution of electric current \mathbf{J}^a and magnetic current \mathbf{J}_m^a . Similarly for \mathbf{E}^b and \mathbf{H}^b generated by \mathbf{J}^b and \mathbf{J}_m^b . Then by the Lorentz reciprocity theorem we get

$$\oint_S (\mathbf{E}^a \times \mathbf{H}^b - \mathbf{E}^b \times \mathbf{H}^a) \cdot d\mathbf{S} = \int_V (\mathbf{E}^b \cdot \mathbf{J}^a - \mathbf{H}^b \cdot \mathbf{J}_m^a - \mathbf{E}^a \cdot \mathbf{J}^b + \mathbf{H}^a \cdot \mathbf{J}_m^b) dV. \quad (2.54)$$

If the current sources are finite and enclosed by the surface S the left side of Eq. (2.54) can be shown to vanish. One of the most useful forms of Lorentz reciprocity theorem in terms of Rumsey's notation [23] may then be expressed as

$$\langle a, b \rangle = \langle b, a \rangle, \quad (2.55)$$

where $\langle a, b \rangle$ is called by Rumsey as *reaction* of the field a onto the current source b and is defined as

$$\langle a, b \rangle = \int_V (\mathbf{E}^a \cdot \mathbf{J}^b - \mathbf{H}^a \cdot \mathbf{J}_m^b) dV. \quad (2.56)$$

Rumsey showed that if the quantity of interest can be expressed as a reaction a variational approximation with a suitable stationary property can be easily derived. To see that we let the correct reaction be $\langle c_a, c_b \rangle$ and the trial reaction be $\langle a, b \rangle$. Then it is shown that if $\langle a, b \rangle$ satisfies the condition

$$\langle c_a, c_b \rangle \approx \langle a, b \rangle = \langle c_a, b \rangle = \langle a, c_b \rangle, \quad (2.57)$$

$\langle a, b \rangle$ is a variational approximation to $\langle c_a, c_b \rangle$ which is stationary with respect to the correct values of c_a and c_b . In order to prove it following Harrington [14] we let

$$a = c_a + p_a e_a, \quad b = c_b + p_b e_b \quad (2.58)$$

where p is an arbitrary parameter and e represents an error. Then $\langle a, b \rangle$ becomes

$$\langle a, b \rangle = \langle c_a, c_b \rangle + p_a \langle e_a, c_b \rangle + p_b \langle c_a, e_b \rangle + p_a p_b \langle e_a, e_b \rangle. \quad (2.59)$$

Using Eq. (2.57) we rewrite the above equation as

$$\langle a, b \rangle = \langle c_a, c_b \rangle - p_a p_b \langle e_a, e_b \rangle. \quad (2.60)$$

Since the equation satisfies

$$\frac{\partial \langle a, b \rangle}{\partial p_a} = \frac{\partial \langle a, b \rangle}{\partial p_b} = 0 \quad \text{as } p_a \rightarrow 0, p_b \rightarrow 0, \quad (2.61)$$

we have proved the stationary property of $\langle a, b \rangle$.

Even if Eq. (2.57) leads us to a variational formula it does not enable us to set up the proper functional equations to be solved when a trial field and associated source

are expanded in series of functions with unknown coefficients. For that purpose we will use the following expression

$$\langle c_a, c_b \rangle \approx \langle a, b \rangle = \frac{\langle a, c_b \rangle \langle c_a, b \rangle}{\langle a, b \rangle}, \quad (2.62)$$

which is the same as Eq. (2.57). By equating these two expressions we are ready to solve for unknown coefficients which is usually equivalent to solving linear algebraic equations. In the final stage by substituting the calculated coefficients into Eq. (2.57) we will have desired results which should be a good approximation to the correct solution.

2.6 Application to Aperture Problem in an Infinite Screen

We consider a surface S which consists of an infinitely thin perfectly conducting plane screen S_2 of infinite extent and an aperture S_1 (or S_a) which is shown in Fig. 2.3.

If we denote the fields as $\mathbf{E}_0(\mathbf{r})$, $\mathbf{H}_0(\mathbf{r})$ in the absence of an aperture we may write the fields in each half-space as

$$\begin{aligned} \mathbf{E}(\mathbf{r}) &= \mathbf{E}_0(\mathbf{r}) + \mathbf{E}_1(\mathbf{r}), & \mathbf{H}(\mathbf{r}) &= \mathbf{H}_0(\mathbf{r}) + \mathbf{H}_1(\mathbf{r}), & z &\leq 0 \\ \mathbf{E}(\mathbf{r}) &= \mathbf{E}_2(\mathbf{r}), & \mathbf{H}(\mathbf{r}) &= \mathbf{H}_2(\mathbf{r}), & z &\geq 0 \end{aligned} \quad (2.63)$$

where the subscripts 1 and 2 indicate the region $z \leq 0$ and $z \geq 0$ respectively and the fields are subject to the boundary condition

$$\mathbf{e}_z \times \mathbf{E} = 0, \quad \mathbf{e}_z \cdot \mathbf{H} = 0, \quad \mathbf{r} \text{ on } S_2. \quad (2.64)$$

\mathbf{E}_0 and \mathbf{H}_0 can be decomposed as

$$\mathbf{E}_0 = \mathbf{E}^{inc} + \mathbf{E}^{ref}, \quad \mathbf{H}_0 = \mathbf{H}^{inc} + \mathbf{H}^{ref}, \quad (2.65)$$

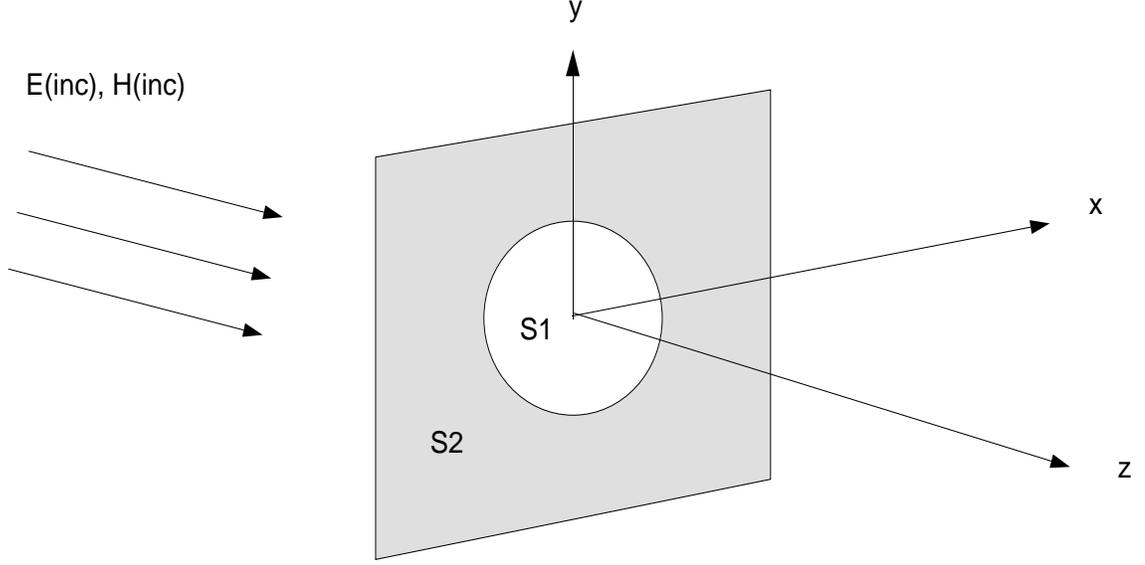

Figure 2.3: Diffracting aperture in a plane screen.

where the superscripts *inc* and *ref* indicate the incident and reflected waves from the plane conducting screen which is not perforated. The boundary conditions on the surface S are

$$E_z^{inc} = E_z^{ref}, \quad H_t^{inc} = H_t^{ref}, \quad \mathbf{r} \text{ on } S, \quad (2.66)$$

where the subscripts z and t denote the z -component (normal component) and the tangential component of fields respectively.

The boundary conditions in the apertures can be expressed by the continuity of fields in the aperture as

$$E_{1t} = E_{2t}, \quad H_{2t} - H_{1t} = H_{0t}, \quad \mathbf{r} \text{ in } S_a, \quad (2.67)$$

$$H_{1z} = H_{2z}, \quad E_{2z} - E_{1z} = E_{0z}, \quad \mathbf{r} \text{ in } S_a, \quad (2.68)$$

which are satisfied if

$$H_{2t} = -H_{1t} = \frac{1}{2}H_{0t} = H_t^{inc}, \quad \mathbf{r} \text{ in } S_a, \quad (2.69)$$

$$E_{2z} = -E_{1z} = \frac{1}{2}E_{0z} = E_z^{inc}, \quad \mathbf{r} \text{ in } S_a. \quad (2.70)$$

Using Eq. (2.46) and Eq. (2.47) we express the fields in each half-space separated by the screen in the integral form as

$$\left. \begin{aligned} \mathbf{E}(\mathbf{r}) &= \nabla \times \int_{S_a} \overline{\mathbf{G}}_m^+(\mathbf{r}|\mathbf{r}') \cdot (\mathbf{e}_z \times \mathbf{E}) dS' \\ \mathbf{H}(\mathbf{r}) &= j\omega\epsilon \int_{S_a} \overline{\mathbf{G}}_m^+(\mathbf{r}|\mathbf{r}') \cdot (\mathbf{e}_z \times \mathbf{E}) dS' \end{aligned} \right\} z \geq 0, \quad (2.71)$$

$$\left. \begin{aligned} \mathbf{E}(\mathbf{r}) &= \mathbf{E}^{inc} + \mathbf{E}^{ref} - \nabla \times \int_{S_a} \overline{\mathbf{G}}_m^-(\mathbf{r}|\mathbf{r}') \cdot (\mathbf{e}_z \times \mathbf{E}) dS' \\ \mathbf{H}(\mathbf{r}) &= \mathbf{H}^{inc} + \mathbf{H}^{ref} - j\omega\epsilon \int_{S_a} \overline{\mathbf{G}}_m^-(\mathbf{r}|\mathbf{r}') \cdot (\mathbf{e}_z \times \mathbf{E}) dS' \end{aligned} \right\} z \leq 0, \quad (2.72)$$

where the superscripts + and - denote the region $z \geq 0$ and $z \leq 0$ respectively. Care must be taken with the sign of unit vector \mathbf{n} . Following our convention that the direction of \mathbf{n} is outwardly normal from the region where the fields are to be calculated $\mathbf{n} = -\mathbf{e}_z$ for the region $z \geq 0$ and $\mathbf{n} = \mathbf{e}_z$ for the region $z \leq 0$.

The dyadic Green's function for the half-space can be readily constructed using the image principle and is shown to be [21] and [29]

$$\overline{\mathbf{G}}_{e,m}^+(\mathbf{r}|\mathbf{r}') = \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \mp \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}' - 2\mathbf{e}_z\mathbf{e}_z \cdot \mathbf{r}') \cdot (\overline{\mathbf{I}} - 2\mathbf{e}_z\mathbf{e}_z), \quad z, z' \geq 0, \quad (2.73)$$

where the upper and lower signs are employed for $\overline{\mathbf{G}}_e^+$ and $\overline{\mathbf{G}}_m^+$ respectively and

$$\overline{\mathbf{G}}^-(\mathbf{r}|\mathbf{r}') = \overline{\mathbf{G}}^+(\mathbf{r} - 2\mathbf{e}_z\mathbf{e}_z \cdot \mathbf{r}, \mathbf{r}' - 2\mathbf{e}_z\mathbf{e}_z \cdot \mathbf{r}'), \quad z, z' \leq 0. \quad (2.74)$$

If Eq. (2.73) is multiplied from the right by the vector $\mathbf{e}_z \times \mathbf{E}(\mathbf{r}')$ and the result evaluated at $z' = 0$ it can be seen that

$$\overline{\mathbf{G}}_m^+(\mathbf{r}|\mathbf{r}') \cdot [\mathbf{e}_z \times \mathbf{E}(\mathbf{r}')] = 2\overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot [\mathbf{e}_z \times \mathbf{E}(\mathbf{r}')]. \quad (2.75)$$

Thus Eqs. (2.71) and (2.72) are rewritten in the form

$$\left. \begin{aligned} \mathbf{E}(\mathbf{r}) &= \nabla \times \int_{S_a} \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot (2\mathbf{e}_z \times \mathbf{E}) dS' \\ \mathbf{H}(\mathbf{r}) &= j\omega\epsilon \int_{S_a} \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot (2\mathbf{e}_z \times \mathbf{E}) dS' \end{aligned} \right\} z \geq 0, \quad (2.76)$$

$$\left. \begin{aligned} \mathbf{E}(\mathbf{r}) &= \mathbf{E}^{inc} + \mathbf{E}^{ref} - \nabla \times \int_{S_a} \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot (2\mathbf{e}_z \times \mathbf{E}) dS' \\ \mathbf{H}(\mathbf{r}) &= \mathbf{H}^{inc} + \mathbf{H}^{ref} - j\omega\epsilon \int_{S_a} \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot (2\mathbf{e}_z \times \mathbf{E}) dS' \end{aligned} \right\} z \leq 0. \quad (2.77)$$

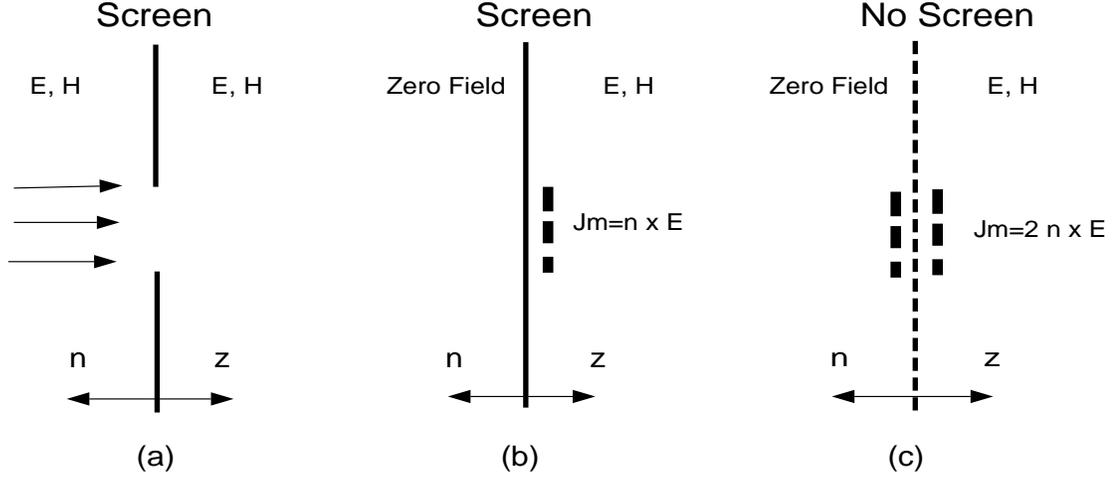

Figure 2.4: (a) Original problem; (b) and (c) Equivalent problem to (a) for the region $z \geq 0$.

The physical steps hidden in the derivation can be visualized from the field equivalence principle shown in Figs. 2.4 and 2.5 for the regions $z \geq 0$ and $z \leq 0$ respectively.

If we know the tangential \mathbf{E} -fields in the aperture Γ we can calculate the fields everywhere using Eqs. (2.76) and (2.77). The desired integral equation for the tangential \mathbf{E} -field in the aperture can be written by noting the boundary conditions Eqs. (2.69) and (2.70). In the plane of the aperture Γ we have

$$\left. \begin{aligned} \mathbf{e}_z \cdot \mathbf{E}^{inc}(\mathbf{r}) &= \mathbf{e}_z \cdot \nabla \times \int_{S_a} \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot (2\mathbf{e}_z \times \mathbf{E}) dS' \\ \mathbf{e}_z \times \mathbf{H}^{inc}(\mathbf{r}) &= j\omega\epsilon \mathbf{e}_z \times \int_{S_a} \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot (2\mathbf{e}_z \times \mathbf{E}) dS' \end{aligned} \right\} \mathbf{r} \in \Gamma \text{ in } S_a. \quad (2.78)$$

In general Γ it is difficult if not impossible to solve this integral equation. Fortunately Γ most of the physically interesting quantities such as the transmission coefficient do not require detailed knowledge of the field around the obstacle. Besides Γ such a quantity is expressed in an integral form which is amenable to an approximation. We take the calculation of the transmission coefficient through a circular aperture as an example of using variational formalism to obtain the approximate solution.

Consider a linearly polarized plane wave normally incident on an aperture in a

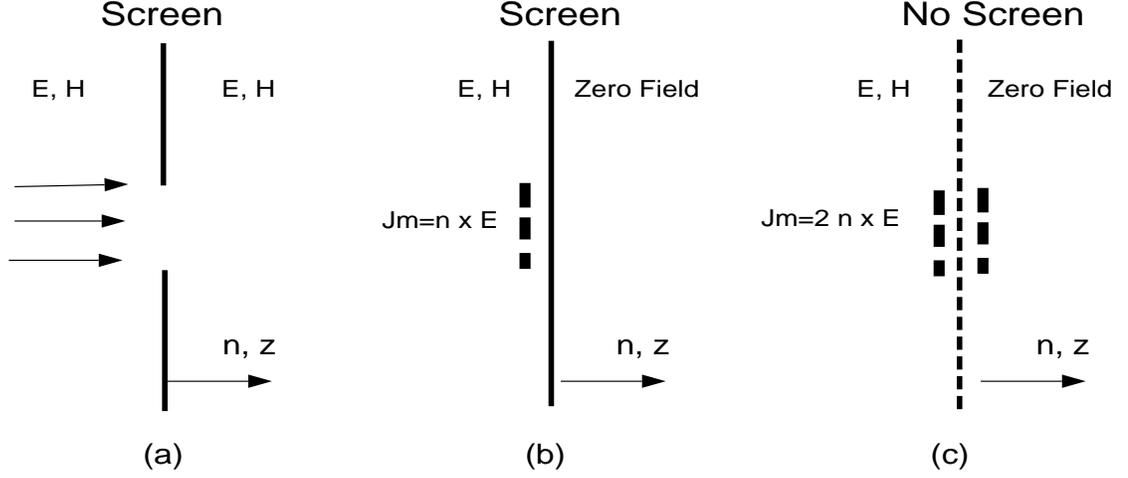

Figure 2.5: (a) Original problem; (b) and (c) Equivalent problem to (a) for the region $z \leq 0$.

plane screen. The transmission coefficient is defined as

$$T = \frac{Re \int_{S_a} \mathbf{E} \times \mathbf{H}^* \cdot \mathbf{e}_z dS}{Re \int_{S_a} \mathbf{E}^{inc} \times \mathbf{H}^{inc*} \cdot \mathbf{e}_z dS}, \quad (2.79)$$

which is the ratio of the transmitted power through an aperture to the power incident on the aperture. Re denotes the real part of the complex quantity. Let the incident wave be specified by

$$Z_0 \mathbf{H}^{inc} = \mathbf{e}_y e^{-jkz}, \quad \mathbf{E}^{inc} = \mathbf{e}_x e^{-jkz}, \quad (2.80)$$

where $Z_0 = \sqrt{\mu_0/\epsilon_0}$ is the intrinsic impedance of free space equal to 377Ω .

Since $\mathbf{e}_z \times \mathbf{H}$ is real in the $z = 0$ plane we may express the numerator of Eq. (2.79) representing the transmitted power as

$$P_t = -Re \int_{S_a} \mathbf{J}_m \cdot \mathbf{H} dS = Re \langle c, c \rangle, \quad (2.81)$$

where $\mathbf{J}_m = \mathbf{n} \times \mathbf{E} = \mathbf{E} \times \mathbf{e}_z$ is the equivalent magnetic surface current in the aperture and $\langle c, c \rangle$ is the Rumsey's notation for the self-reaction of the correct magnetic

current radiating in the presence of an electric conducting screen. We approximate $\langle c, c \rangle$ by $\langle a, a \rangle$ with the constraint given by Eq. (2.57) such that

$$\langle c, c \rangle \approx \langle a, a \rangle = \langle c, a \rangle = \langle a, c \rangle. \quad (2.82)$$

The meaning of $\langle c, a \rangle$ is restated as the reaction of the correct field \mathbf{H} on the trial current \mathbf{J}_m^a . The constraint condition is met for our problem because $\mathbf{n} \times \mathbf{H}^c = \mathbf{n} \times \mathbf{H}^{inc}$ in the aperture. A variational formula for $\langle c, c \rangle \Gamma$ which is stationary with respect to the correct magnetic current $\mathbf{J}_m^c \Gamma$ may be written as

$$\langle c, c \rangle \approx \frac{\langle c, a \rangle^2}{\langle a, a \rangle} = -\frac{\left(\int_{S_a} \mathbf{H}^{inc} \cdot \mathbf{J}_m^a dS \right)^2}{\int_{S_a} \mathbf{H}^a \cdot \mathbf{J}_m^a dS}, \quad (2.83)$$

where we must emphasize that \mathbf{H}^a is the field due to the assumed current \mathbf{J}_m^a .

Thus the variational solution of the transmission coefficient is

$$T = \frac{-1}{Z_0 A} \text{Re} \frac{\left(\int_{S_a} \mathbf{H}^{inc} \cdot \mathbf{J}_m^a dS \right)^2}{\int_{S_a} \mathbf{H}^a \cdot \mathbf{J}_m^a dS}, \quad (2.84)$$

where $P_i = Z_0 A$ represents the incident power on the aperture of area A .

As a choice of trial fields Γ Meixner has shown that Γ at the rim of an aperture Γ the tangential component of the electric field vanishes as $R^{1/2}$ and the normal component increases as $R^{-1/2}$ where R measures the distance from the field point to the edge. Bouwkamp has obtained the low-frequency exact solution for the normal incidence on the circular hole of radius a . According to him Γ

$$\begin{aligned} \mathbf{e}_\rho \cdot \mathbf{E}(\rho, \phi) &= \frac{2a^2 - \rho^2}{(a^2 - \rho^2)^{1/2}} \cos \phi, \\ \mathbf{e}_\phi \cdot \mathbf{E}(\rho, \phi) &= -2(a^2 - \rho^2)^{1/2} \sin \phi, \end{aligned}$$

in the hole. Here the origin of the polar coordinate system is at the center of the

circular hole. Thus we may choose the trial field in the aperture in the form

$$\mathbf{e}_\rho \cdot \mathbf{E}(\rho, \phi) = \frac{1}{(1 - \frac{\rho^2}{a^2})^{1/2}} \sum_0^\infty a_n \left(\frac{\rho}{a}\right)^{2n} \cos \phi, \quad (2.85)$$

$$\mathbf{e}_\phi \cdot \mathbf{E}(\rho, \phi) = \left(1 - \frac{\rho^2}{a^2}\right)^{1/2} \sum_0^\infty b_n \left(\frac{\rho}{a}\right)^{2n} \sin \phi, \quad (2.86)$$

where a_n and b_n are unknown coefficients to be determined. Huang and Kodis and Levine [15] have used this trial field to calculate the transmission coefficient and have shown that the agreement between the calculation and measurement is excellent.

As an example of calculational procedure we adopt here a simpler form of the original trial function used by Levine and Schwinger [21]. With the incident field specified in Eq. (2.80) we may assume a one-component trial field as

$$\mathbf{n} \times \mathbf{E}^a = \mathbf{e}_x \sum_1^\infty a_n \left(1 - \frac{\rho^2}{a^2}\right)^{n-1/2} = \mathbf{e}_x \phi(\rho). \quad (2.87)$$

Substituting this into Eq. (2.84) and using the relation

$$\mathbf{H}(\mathbf{r})^a = -2j\omega\epsilon \int_{S_a} \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot [\mathbf{n} \times \mathbf{E}^a(\mathbf{r}')] dS', \quad (2.88)$$

we obtain

$$\begin{aligned} T &= \frac{1}{Z_0 A} \text{Re} I \\ &= \frac{1}{Z_0 A} \text{Re} \frac{(\int_{S_a} \phi(\rho) ds)^2}{j\omega\epsilon \int_{S_a} \int_{S_a} \phi(\rho)(G_{xx} + G_{yy})\phi(\rho') dS dS'}. \end{aligned} \quad (2.89)$$

If we denote

$$B_n = \int_{S_a} \left(1 - \frac{\rho^2}{a^2}\right)^{n-1/2} dS = \frac{2\pi a^2}{2n+1} \quad (2.90)$$

and

$$\begin{aligned} C_{mn} &= \int_{S_a} \int_{S_a} \left(1 - \frac{\rho^2}{a^2}\right)^{m-1/2} (G_{xx} + G_{yy}) \left(1 - \frac{\rho'^2}{a^2}\right)^{n-1/2} dS dS' \\ &= C_{nm}, \end{aligned} \quad (2.91)$$

we may rewrite Eq. (2.89) as

$$(j\omega\epsilon)I \sum_{m,n=1}^{\infty} a_m a_n C_{mn} = \left(\sum_{n=1}^{\infty} a_n B_n \right)^2. \quad (2.92)$$

The procedure for determining unknown coefficients a_n is to differentiate I with respect to each coefficient a_ν and set $\partial I / \partial a_\nu = 0$. This leads to

$$(j\omega\epsilon)I \sum_m C_{nm} a_m = B_n \left(\sum_m a_m B_m \right). \quad (2.93)$$

But by definition $I = \sum_n a_n B_n \Gamma$ so that we have a set of linear algebraic equations for $a_m \Gamma$

$$\sum_{m=1}^{\infty} C_{nm} a_m = \frac{B_n}{j\omega\epsilon}. \quad (2.94)$$

Once a_m is determined the transmission coefficient will be obtained from

$$T^{(N)} = \frac{1}{Z_0 A} Re \sum_{n=1}^N I = \frac{1}{Z_0 A} Re \sum_{n=1}^N a_n B_n, \quad (2.95)$$

where N denotes the order of approximation and Re denotes the real part.

As an example we will work out the first-order approximation. For $N = 1$ a_1 is simply $j\omega\epsilon a_1 = B_1 / C_{11}$. Levine and Schwinger [21] have shown that the coefficients C_{mn} can be expressed as

$$C_{mn} = \frac{\pi}{2} \left(\frac{2}{ka} \right)^2 a^3 \Gamma \left(m + \frac{1}{2} \right) \Gamma \left(n + \frac{1}{2} \right) [(m+n-3)F_{mn}(ka) - kaF'_{mn}(ka)], \quad (2.96)$$

where a is the radius of a circular hole and the prime denotes differentiation with respect to the argument. The function $F_{mn}(\alpha)$ has been considered in Ref.[19Γ20] and its explicit expression is given there for $m, n = 1, 2$. Then with Eq. (2.95) $T^{(1)}$ becomes

$$T^{(1)} = -\frac{8}{9\pi} ka Im \frac{1}{F_{11}(ka) + kaF'_{11}(ka)}, \quad (2.97)$$

which is exactly the same as Eq. (7.16) in Ref. [21] except for the sign because we have used $e^{j\omega t}$ instead of $e^{-i\omega t}$ in Ref. [21]. We also point out the differences between Levine and Schwinger's work and ours in deriving Eq. (2.97). First we used Rumsey's reaction concept to derive the variational formula. Second we used *M.K.S.* units instead of *cgs* units. Because of these differences the intermediate results in deriving Eq. (2.97) look different but the final results are of the same form.

The transmission coefficients obtained from the various theories which are expanded in powers of ka are:

1. Small hole approximation (due to Bethe [5])

$$T = \frac{64}{27\pi^2}(ka)^4. \quad (2.98)$$

2. First- and second-order approximations by the variational method using Eq. (2.87) as the trial fields (due to Levine and Schwinger [21])

$$T^{(1)} = \frac{64}{27\pi^2}(ka)^4 \left[1 + \frac{27}{25}(ka)^2 + 0.72955(ka)^4 + \dots \right], \quad (2.99)$$

$$T^{(2)} = \frac{64}{27\pi^2}(ka)^4 \left[1 + \frac{27}{25}(ka)^2 + 0.74155(ka)^4 + \dots \right]. \quad (2.100)$$

3. Zeroth-order approximation by the variational method using Eqs. (2.85) and (2.86) as the trial fields (due to Levine and Schwinger [21])

$$T^{(0)} = \frac{64}{27\pi^2}(ka)^4 \left[1 + \frac{22}{25}(ka)^2 + 0.4079(ka)^4 + \dots \right]. \quad (2.101)$$

4. First-order approximation by the variational method using Eqs. (2.85) and (2.86) as the trial fields (due to Huang, Kodis and Levine [15])

$$T^{(1)} = \frac{64}{27\pi^2}(ka)^4 \left[1 + \frac{22}{25}(ka)^2 + 0.3968(ka)^4 + \dots \right]. \quad (2.102)$$

5. Exact solution (due to Bouwkamp [3])

$$T = \frac{64}{27\pi^2}(ka)^4 \left[1 + \frac{22}{25}(ka)^2 + 0.3979(ka)^4 + \dots \right]. \quad (2.103)$$

(Original work of Bouwkamp is not available to us but the above result is cited in Ref. [15Γ21].)

We note that Bethe's result is accurate only at low frequencies namely $ka \ll 1$. The variational method using one of the simplest trial fields shows a good agreement with the exact result even when such a trial field does not incorporate the proper two-component tangential electric fields in the aperture. Inclusion of two-component effects raises the accuracy up to the relative order $(ka)^2$ even in zeroth-order approximation as shown in Eq. (2.101). This demonstrates the importance of choosing correct trial fields.

Chapter 3

Longitudinal Impedance of a Hole in an Infinite Screen

3.1 Introduction

In this chapter we evaluate the longitudinal impedance of a hole in a thin perfectly conducting plane screen. We have already discussed a similar problem of calculating the transmission coefficient in Chapter 2. Since the analytical technique presented in Chapter 2 is general enough to deal with the calculation of a variety of interesting quantities it is not necessary to introduce new formalisms for our impedance calculation. After all calculating the impedance or the transmission coefficient deals with the same diffraction phenomenon. Only the definitions which involve the integration of fields are different.

In Section 3.2 we will estimate the impedance in the low frequency range using Bethe's [5] small hole approximation. If we can expand in powers of frequency the low frequency solution will represent the first term in the series.

In Section 3.3 we will obtain the variational solution of impedance with different trial fields showing the main result of this chapter.

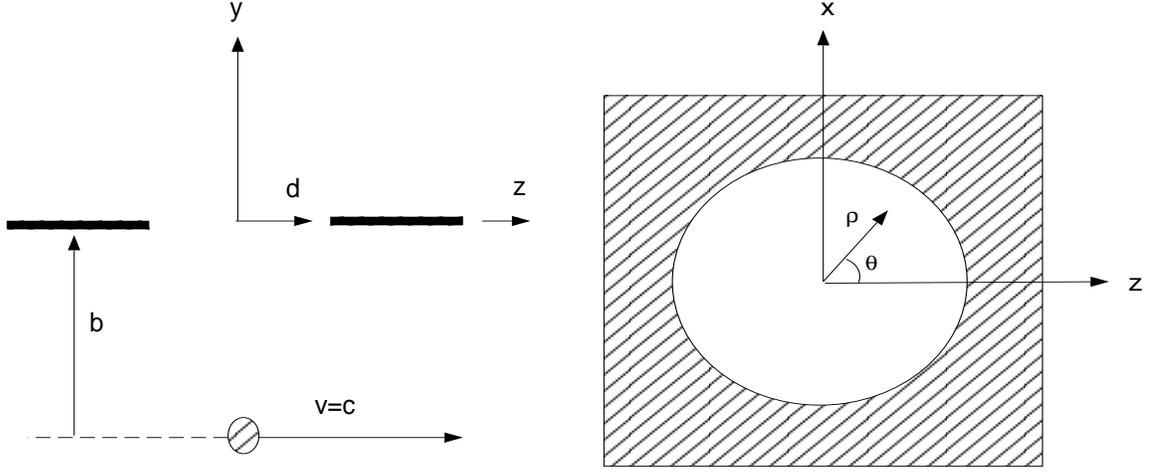

Figure 3.1: Infinite flat screen with a hole.

3.2 Low Frequency Solution

The geometry of our problem is shown in Fig. 3.1 where a charge is moving in the z -direction with velocity close to the speed of light. The distance between the plane screen and the beam path is b and the origin of the coordinate is at the center of the hole with radius d . The local cylindrical coordinate system (ρ, θ, y) is also shown.

Denoting $\mathbf{E}_1\Gamma\mathbf{H}_1$ as the fields without the hole and $\mathbf{E}_2\Gamma\mathbf{H}_2$ as the fields with the hole we can express the longitudinal coupling impedance defined by Eq. (1.14) as

$$|I_0|^2 Z(k) = \int_{hole} (\mathbf{n} \times \mathbf{E}_2) \cdot \mathbf{H}_1^* dS, \quad (3.1)$$

where $\mathbf{J}_m = \mathbf{n} \times \mathbf{E}_2$ is the magnetic current induced in the hole which is not known until we solve the problem. In the low frequency approximation however we may use Bethe's solution for $\mathbf{n} \times \mathbf{E}$ as follows.

Assuming a small hole namely $kd = 2\pi d/\lambda \ll 1$ Bethe obtained the solution for

the magnetic current in the hole [5]

$$\mathbf{n} \times \mathbf{E} = -\frac{\rho}{\pi\sqrt{d^2 - \rho^2}} \mathbf{e}_\rho \times \mathbf{E}_0 + j\frac{2kZ_0}{\pi}\sqrt{d^2 - \rho^2} \mathbf{H}_0 = \mathbf{J}_{m,E} + \mathbf{J}_{m,H}, \quad (3.2)$$

where \mathbf{E}_0 and \mathbf{H}_0 are the field evaluated at the center of the hole in the absence of the hole and $\mathbf{J}_{m,E}$ and $\mathbf{J}_{m,H}$ denote the magnetic current induced in the hole due to the incident electric and magnetic field respectively.

The magnetic field from the unit source current can be obtained using the image principle resulting in

$$\begin{aligned} H_x &= \frac{I_0}{2\pi} \left[\frac{(y-b)}{x^2 + (y-b)^2} - \frac{(y+b)}{x^2 + (y+b)^2} \right] e^{-jkz}, \\ H_z &= \frac{I_0}{2\pi} \left[\frac{x}{x^2 + (y+b)^2} - \frac{x}{x^2 + (y-b)^2} \right] e^{-jkz}, \end{aligned} \quad (3.3)$$

where the coordinate system in Fig. 3.1 is used. In the plane of the hole it becomes

$$H_x = -\frac{I_0}{\pi} \frac{b}{x^2 + b^2} e^{-jkz}, \quad H_z = 0. \quad (3.4)$$

Assuming a small hole in which the field is uniform but the phase is varying we may rewrite the source field as

$$\mathbf{H}_1 = \mathbf{H}_0 - jkz\mathbf{H}_0 + \mathcal{O}(k^2), \quad \text{where } \mathbf{H}_0 = -\frac{I_0}{\pi b}\mathbf{e}_x. \quad (3.5)$$

Then the longitudinal coupling impedance becomes

$$|I_0|^2 Z_H(k) = \int_{hole} \mathbf{J}_{m,H} \cdot \mathbf{H}_1^* dS = j\frac{4Z_0 d^3 H_0^2}{3} k, \quad (3.6)$$

$$|I_0|^2 Z_E(k) = \int_{hole} \mathbf{J}_{m,E} \cdot \mathbf{H}_1^* dS = -j\frac{2Z_0 d^3 H_0^2}{3} k, \quad (3.7)$$

$$|I_0|^2 Z(k) = Z_H(k) + Z_E(k) = j\frac{2Z_0 d^3 H_0^2}{3} k, \quad (3.8)$$

which results in $Z(k) = (2Z_0d^3/3\pi^2b^2)k$. We note that $Z_H(k)$ due to $\mathbf{J}_{m,H}$ is a factor of two larger than $Z(k)$ and $Z_E(k)$ due to $\mathbf{J}_{m,E}$ is the negative of $Z(k)$. We also observe that the current I_0 does not appear in the final expression of impedance. Thus we keep I_0 in the expression only for bookkeeping purposes setting $I_0 = 1$ in the final formula. By doing so we may simplify the expression in the later sections.

Although Eq. (3.8) is valid only for low frequencies it is quite general. If we consider a charge traveling inside a cylindrical beam pipe of radius b with a hole of radius d the longitudinal coupling impedance becomes with $H_0 = \frac{I_0}{2\pi b}$ in Eq. (3.8)

$$Z(k) = j \frac{Z_0 d^3}{6\pi^2 b^2} k \quad (3.9)$$

which is exactly the same as Kurennoy's [18] and Gluckstern's results [11].

Thus in low frequency approximation we can easily obtain the longitudinal coupling impedance once we know the source field which is specific to the geometry surrounding a traveling charge.

3.3 Variational Solutions

In this section we try to calculate the longitudinal coupling impedance of a hole in an infinite screen using a variational method. We begin by defining an "impedance functional" which is stationary with respect to the unknown quantity (magnetic current density in the hole). Such a functional may not be the same as the quantity of interest the longitudinal coupling impedance but it will be shown later that the two quantities are related. Thus from the impedance functional we can obtain the expression for the longitudinal coupling impedance. Various trial fields are used to evaluate the impedance functional and the results are presented.

3.3.1 Derivation of Impedance Functional

The geometry of the problem is shown in Fig. 3.1. If we denote the fields without the hole in the screen as \mathbf{E}_1 and \mathbf{H}_1 and the fields with the hole in the screen as \mathbf{E}_2 and \mathbf{H}_2 and $\mathbf{E}_{1,2}$ and $\mathbf{H}_{1,2}$ satisfy Maxwell's equations in the form

$$\nabla \times \mathbf{E}_{1,2} = -j\omega\mu\mathbf{H}_{1,2}, \quad \nabla \times \mathbf{H}_{1,2} = j\omega\epsilon\mathbf{E}_{1,2} + \mathbf{J}, \quad (3.10)$$

where $\mathbf{J} = \mathbf{e}_z\delta(y+d)\delta(x)e^{-jkz}$ is the current density of the driving beam with unit amplitude and $k = \omega\sqrt{\epsilon_0\mu_0}$ is the free-space wave number.

Expanding the quantity $\nabla \cdot (\mathbf{E}_1 \times \mathbf{H}_2 - \mathbf{E}_2 \times \mathbf{H}_1)$ we get the identity

$$\nabla \cdot (\mathbf{E}_1 \times \mathbf{H}_2 - \mathbf{E}_2 \times \mathbf{H}_1) = \mathbf{J} \cdot (\mathbf{E}_2 - \mathbf{E}_1). \quad (3.11)$$

Taking the integral of both sides we have

$$\int (\mathbf{E}_1 \times \mathbf{H}_2 - \mathbf{E}_2 \times \mathbf{H}_1) \cdot \mathbf{n} dS = \int \mathbf{J} \cdot (\mathbf{E}_2 - \mathbf{E}_1) dV. \quad (3.12)$$

We define the impedance functional \mathcal{Z} as

$$\mathcal{Z} = - \int \mathbf{J} \cdot (\mathbf{E}_2 - \mathbf{E}_1) dV. \quad (3.13)$$

In the above definition as we subtracted the contribution from the source field the entire contribution is from the scattered field which satisfies the homogeneous Maxwell's equations. We note that if the electric field is real the longitudinal impedance is the complex conjugate of the impedance functional $Z(k) = \mathcal{Z}^*(k)$.

If the integrating surface is chosen to coincide with the plane of the screen where \mathbf{E}_1 satisfies the boundary condition $\mathbf{n} \times \mathbf{E}_1 = 0$ \mathcal{Z} reduces to

$$\mathcal{Z} = \int \mathbf{H}_1 \cdot (\mathbf{n} \times \mathbf{E}_2) dS, \quad (3.14)$$

which we want to evaluate. We also recall that the longitudinal impedance is

$$Z(k) = \int \mathbf{H}_1^* \cdot (\mathbf{n} \times \mathbf{E}_2) dS. \quad (3.15)$$

For the sake of clarity we change the notation as

$$\begin{aligned} \mathbf{E}_1 &= \mathbf{E}^i, & \mathbf{H}_1 &= \mathbf{H}^i, \\ \mathbf{E}_2 &= \mathbf{E}^i + \mathbf{E}^s, & \mathbf{H}_2 &= \mathbf{H}^i + \mathbf{H}^s, \end{aligned}$$

where superscript i denotes the “incident” or “source” field of the driving beam without the hole and superscript s denotes the “scattered” field from the hole. The hole is acting as “scattering object” or “obstacle”; otherwise the media are empty space surrounded or separated by the perfectly conducting material.

In the new notation we may write \mathcal{Z} as

$$\mathcal{Z} = \int \mathbf{H}^i \cdot (\mathbf{n} \times \mathbf{E}^s) dS, \quad (3.16)$$

where $\mathbf{n} \times \mathbf{E}^i = 0$ in the aperture is used. With $\mathbf{J}_m = \mathbf{n} \times \mathbf{E}^s$ \mathcal{Z} becomes

$$\mathcal{Z} = \int \mathbf{H}^i \cdot \mathbf{J}_m dS. \quad (3.17)$$

But by definition $\mathcal{Z} = - \int \mathbf{J} \cdot \mathbf{E}^s dS$ so that this satisfies Lorentz’s reciprocity theorem. Using Rumsey’s notation we may express \mathcal{Z} in a compact form $\mathcal{Z} = - \langle i, s \rangle$ which is often called the “echo” of a scattering object an important quantity in the development of radar technology. We can state that our impedance functional is the mutual reaction between the source current and the magnetic current induced in the aperture. Using known boundary conditions which the tangential magnetic field must satisfy in the aperture $H_t^i = -2H_t^s$ we rewrite

$$\mathcal{Z} = -2 \int \mathbf{H}^s \cdot \mathbf{J}_m dS = 2 \langle c, c \rangle, \quad (3.18)$$

where $\langle c, c \rangle$ stands for the self-reaction of the “correct” magnetic current induced in the aperture by the source.

Now we can write the variational expression for \mathcal{Z} as

$$\mathcal{Z} = 2 \langle c, c \rangle \approx 2 \frac{\langle c, a \rangle^2}{\langle a, a \rangle} = \frac{-1}{2} \frac{\left[\int_{S_a} \mathbf{H}^i \cdot (\mathbf{n} \times \mathbf{E}^a) dS \right]^2}{\int_{S_a} \mathbf{H}^a \cdot (\mathbf{n} \times \mathbf{E}^a) dS}. \quad (3.19)$$

Using dyadic Green’s function $\overline{\mathbf{G}}$ we calculate \mathbf{H}^a from

$$\mathbf{H}^a(\mathbf{r}) = -2j\omega\epsilon \int_{S_a} \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot [\mathbf{n} \times \mathbf{E}^a(\mathbf{r}')] dS'. \quad (3.20)$$

Thus Eq. (3.19) may be rewritten as

$$\mathcal{Z} = \frac{1}{4j\omega\epsilon} \frac{\left[\int_{S_a} \mathbf{H}^i \cdot (\mathbf{n} \times \mathbf{E}^a) dS \right]^2}{\int_{S_a} \int_{S_a} [\mathbf{n} \times \mathbf{E}^a(\mathbf{r})] \cdot \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot [\mathbf{n} \times \mathbf{E}^a(\mathbf{r}')] dS dS'} \quad (3.21)$$

which is a homogeneous equation in the sense that the result does not depend on the amplitude of the assumed electric field \mathbf{E}^a . In fact this is a general expression for the impedance functional of an aperture in a conducting plane as long as the plane is the symmetry plane separating two regions namely an infinite plane or coupled waveguide structure. Details of the calculation depend on the shape of the aperture and the assumed tangential electric field in the aperture. In the next section we present a closed form solution for a hole in an infinite screen.

3.3.2 The First Variational Solution

In the previous section we derived the impedance functional \mathcal{Z} which is stationary with respect to the correct tangential electric field in the aperture. In order to evaluate it we need to assume a trial function for \mathbf{E}^a .

We assume a one-component trial field based on Bethe’s solution [5] as

$$\mathbf{n} \times \mathbf{E} = \mathbf{e}_x \sum_{n=1}^{n=\infty} a_n \left(1 - \frac{\rho^2}{d^2}\right)^{n-\frac{1}{2}} = \mathbf{e}_x \phi(\rho), \quad (3.22)$$

where we dropped the superscript a . We note that the unknown coefficient a_n is dependent on the frequency. The impedance functional is

$$\mathcal{Z} = \frac{1}{4j\omega\epsilon} \frac{\left[\int_{S_a} H_x^i(\rho, \theta) \phi(\rho) dS \right]^2}{\int_{S_a} \int_{S_a} \phi(\rho) G_{xx}(\rho, \theta | \rho', \theta') \phi(\rho') dS dS'}. \quad (3.23)$$

We transform the equation into a more symmetrical form utilizing the symmetry of a circle. For instance if the beam is moving in the x direction the expression for \mathcal{Z} will be in the same functional form as Eq. (3.23) except that the subscript x denoting the x component of the field or dyadic Green's function is replaced by z . Thus we have

$$\mathcal{Z} = \frac{1}{2j\omega\epsilon} \frac{\left[\int_{S_a} H_x^i(\rho, \theta) \phi(\rho) dS \right]^2}{\int_{S_a} \int_{S_a} \phi(\rho) (G_{xx} + G_{zz}) \phi(\rho') dS dS'}, \quad (3.24)$$

which is later shown to be much simpler to evaluate.

If we define

$$B_n = \int H_x^i(\rho, \theta) \left(1 - \frac{\rho^2}{d^2}\right)^{n-\frac{1}{2}} dS \quad (3.25)$$

and

$$C_{mn} = \int \int \left(1 - \frac{\rho^2}{d^2}\right)^{m-\frac{1}{2}} (G_{xx} + G_{zz}) \left(1 - \frac{\rho'^2}{d^2}\right)^{n-\frac{1}{2}} dS dS' = C_{nm}, \quad (3.26)$$

\mathcal{Z} becomes

$$\mathcal{Z} = \frac{1}{2j\omega\epsilon} \frac{(\sum_{n=1} a_n B_n)^2}{\sum_{n,m=1} a_m a_n C_{mn}}, \quad (3.27)$$

or

$$(2j\omega\epsilon)\mathcal{Z} \sum_{n,m=1} a_m a_n C_{mn} = \left(\sum_n a_n B_n \right)^2. \quad (3.28)$$

Differentiation with respect to a_ν and utilization of the stationary property of \mathcal{Z} namely $\partial\mathcal{Z}/\partial a_\nu = 0$ yield

$$(2j\omega\epsilon) \sum_m a_m C_{mn} = B_n, \quad (3.29)$$

where we used the identity $\mathcal{Z} = \sum_n a_n B_n$. Once the frequency-dependent coefficient a_n is determined by solving the linear algebraic equation Eq. (3.29) the desired impedance functional can be obtained from

$$\mathcal{Z}^{(N)} = \sum_{n=1}^N a_n B_n, \quad (3.30)$$

where N is the order of approximation. Since the longitudinal coupling impedance is defined by $Z(k) = \sum_{n=1}^N a_n B_n^*$ and $B_n = B_n^*$ which will be shown later the impedance functional is the same as the longitudinal coupling impedance.

The lowest order approximation $N = 1$ results in

$$\begin{aligned} a_1 &= \frac{B_1}{2j\omega\epsilon C_{11}}, \\ \mathcal{Z}^{(1)} &= -j \frac{Z_0}{2k} \left(\frac{B_1^2}{C_{11}} \right), \end{aligned} \quad (3.31)$$

where $k = \omega\sqrt{\epsilon_0\mu_0}$ is the free-space wave number and $Z_0 = 377 \Omega$.

With $N=2$ we find

$$\begin{aligned} a_1 &= -j \frac{Z_0}{2k} \left[\frac{B_1 C_{22} - B_2 C_{12}}{C_{11} C_{22} - C_{12}^2} \right], \\ a_2 &= -j \frac{Z_0}{2k} \left[\frac{B_2 C_{11} - B_1 C_{12}}{C_{11} C_{22} - C_{12}^2} \right], \\ \mathcal{Z}^{(2)} &= -j \frac{Z_0}{2k} \left[\frac{B_1^2}{C_{11}} + \frac{(B_2 C_{11} - B_1 C_{12})^2}{C_{11}(C_{11} C_{22} - C_{12}^2)} \right] \\ &= \mathcal{Z}^{(1)} - j \frac{Z_0}{2k} \frac{(B_2 C_{11} - B_1 C_{12})^2}{C_{11}(C_{11} C_{22} - C_{12}^2)}, \end{aligned} \quad (3.32)$$

which shows the successive approximation as the order of approximation is increased.

We turn our attention to finding an explicit expression of the quantities B_n and C_{mn} in order to complete the approximate calculation of the impedance. Since the most convenient coordinate system to describe the hole in the flat plane is the cylindrical coordinate system we express the component of dyadic Green's function in

that coordinate system and then carry out the necessary integration to obtain B_n and C_{mn} .

The free-space Green's function satisfying the wave equation

$$(\nabla^2 + k^2)G(\mathbf{r}, \mathbf{r}') = -\delta(\mathbf{r} - \mathbf{r}')$$

is $G = e^{-jkR}/4\pi R\Gamma$ where $R = |\mathbf{r} - \mathbf{r}'|$. Its integral representation is

$$\begin{aligned} G &= \frac{e^{-jkR}}{4\pi R} \\ &= \frac{1}{8\pi^3} \int dq_x e^{-jq_x(x-x')} \int dq_z e^{-jq_z(z-z')} \int dq_y \frac{e^{-jq_y(y-y')}}{q_x^2 + q_z^2 + q_y^2 - k^2}, \end{aligned} \quad (3.33)$$

where the Cartesian coordinate system is defined in Fig. 3.1. With the help of a contour which will result in the outgoing wave satisfying the radiation condition at infinity Eq. (3.33) becomes

$$G = \frac{1}{8\pi^2} \int \int dq_x dq_z \frac{e^{-j[q_x(x-x') + q_z(z-z') + \sqrt{k^2 - q_x^2 - q_z^2}|y-y'|]}}{\sqrt{q_x^2 + q_z^2 - k^2}}. \quad (3.34)$$

For the convergence of the above integral we require that $Im\sqrt{k^2 - q_x^2 - q_z^2}$ is negative which also implies $Im\sqrt{q_x^2 + q_z^2 - k^2}$ positive.

We are now ready to evaluate the individual component of dyadic Green's function. Specifically we will work out G_{xx} and G_{zz} .

$$\begin{aligned} G_{zz} &= \left(1 + \frac{1}{k^2} \frac{\partial^2}{\partial z^2}\right) G \\ &= \frac{1}{8\pi^2} \int \int dq_x dq_z \frac{e^{-j[q_x(x-x') + q_z(z-z') + \sqrt{k^2 - q_x^2 - q_z^2}|y-y'|]}}{\sqrt{q_x^2 + q_z^2 - k^2}} \left(1 - \frac{q_z^2}{k^2}\right). \end{aligned} \quad (3.35)$$

Introducing a set of angle variables

$$\begin{aligned} \mathbf{q} &= q_z \mathbf{e}_z + q_x \mathbf{e}_x = (q \cos u) \mathbf{e}_z + (q \sin u) \mathbf{e}_x, \\ \mathbf{R} &= (z - z') \mathbf{e}_z + (x - x') \mathbf{e}_x = (R \cos v) \mathbf{e}_z + (R \sin v) \mathbf{e}_x, \end{aligned}$$

we obtain

$$G_{zz} = \frac{1}{8\pi^2} \int_0^\infty \frac{q dq}{\sqrt{q^2 - k^2}} e^{-j\sqrt{k^2 - q^2}|y - y'|} \int_0^{2\pi} e^{-jqR \cos(v-u)} du$$

$$- \frac{1}{8\pi^2} \int_0^\infty \frac{q dq}{\sqrt{q^2 - k^2}} \left(\frac{q^2}{k^2}\right) e^{-j\sqrt{k^2 - q^2}|y - y'|} \int_0^{2\pi} e^{-jqR \cos(v-u)} \cos^2 u du.$$

Using an integral formula

$$\int_0^\pi e^{\pm jz \cos \theta} \sin^{2\nu} \theta d\theta = \frac{\Gamma(\nu + \frac{1}{2})\Gamma(\frac{1}{2})}{(z/2)^\nu} J_\nu(z), \quad (3.36)$$

we find

$$G_{zz} = \frac{1}{4\pi} \int_0^\infty \frac{q dq}{\sqrt{q^2 - k^2}} \left[J_0(qR) - \frac{q^2}{2k^2} (J_0(qR) - \cos 2v J_2(qR)) \right] e^{-j\sqrt{k^2 - q^2}|y - y'|}. \quad (3.37)$$

A similar expression for G_{xx} is

$$G_{xx} = \frac{1}{4\pi} \int_0^\infty \frac{q dq}{\sqrt{q^2 - k^2}} \left[J_0(qR) - \frac{q^2}{2k^2} (J_0(qR) + \cos 2v J_2(qR)) \right] e^{-j\sqrt{k^2 - q^2}|y - y'|}. \quad (3.38)$$

On the aperture plane $y = y' = 0$ the desired expression for $G_{xx} + G_{zz}$ takes a simpler form

$$G_{xx} + G_{zz} = \left[\left(1 + \frac{1}{k^2} \frac{\partial^2}{\partial x^2}\right) + \left(1 + \frac{1}{k^2} \frac{\partial^2}{\partial z^2}\right) \right] G$$

$$= \frac{1}{4\pi} \int_0^\infty q dq \left[(q^2 - k^2)^{-1/2} - \frac{1}{k^2} (q^2 - k^2)^{1/2} \right] J_0(qR). \quad (3.39)$$

Using a Bessel function addition theorem

$$J_0(qR) = J_0\left(q(\rho^2 + \rho'^2 - 2\rho\rho' \cos(\theta - \theta'))^{1/2}\right)$$

$$= \sum_0^\infty (2 - \delta_{0n}) J_n(q\rho) J_n(q\rho') \cos n(\theta - \theta'),$$

where $\delta_{0n} = 1$ if $n = 0$ and $\delta_{0n} = 0$ if $n \neq 0$ we further transform $G_{xx} + G_{zz}$ as

$$G_{xx} + G_{zz} = \frac{1}{4\pi} \sum_0^{\infty} (2 - \delta_{0n}) \cos n(\theta - \theta') \int_0^{\infty} q dq \left[(q^2 - k^2)^{-1/2} - \frac{1}{k^2} (q^2 - k^2)^{1/2} \right] J_n(q\rho) J_n(q\rho').$$

Substituting the above expression into Eq. (3.26) we have

$$C_{mn} = \pi \int_0^{\infty} \left[(q^2 - k^2)^{-1/2} - \frac{1}{k^2} (q^2 - k^2)^{1/2} \right] \cdot \int_0^d \rho \left(1 - \frac{\rho^2}{d^2} \right)^{m-\frac{1}{2}} J_0(q\rho) d\rho \int_0^d \rho' \left(1 - \frac{\rho'^2}{d^2} \right)^{n-\frac{1}{2}} J_0(q\rho') d\rho' \quad (3.40)$$

which is to be evaluated.

With the change of variable $\rho = d \sin \varphi$ the first integral in Eq. (3.40) becomes

$$\begin{aligned} \int_0^d \rho \left(1 - \frac{\rho^2}{d^2} \right)^{m-\frac{1}{2}} J_0(q\rho) d\rho &= d^2 \int_0^{\frac{\pi}{2}} J_0(qd \sin \varphi) \sin \varphi \cos^{2m} \varphi d\varphi \\ &= d^2 \frac{2^{m-\frac{1}{2}} \Gamma(m + \frac{1}{2})}{(qd)^{m+\frac{1}{2}}} J_{m+\frac{1}{2}}(qd), \end{aligned} \quad (3.41)$$

where in deriving the final result we used Sonine's first finite integral formula¹

$$\int_0^{\frac{\pi}{2}} J_{\mu}(z \sin \theta) \sin^{\mu+1} \theta \cos^{2\nu+1} \theta d\theta = \frac{2^{\nu} \Gamma(\nu + 1)}{z^{\nu+1}} J_{\mu+\nu+1}(z) \quad (3.42)$$

which is valid when both $Re(\mu)$ and $Re(\nu)$ exceed -1.

Substituting the above intermediate result into Eq. (3.40) and introducing a new variable $v = q/k$ we rewrite C_{mn} as

$$C_{mn} = \frac{\pi}{2} \left(\frac{2}{kd} \right)^{m+n} d^3 \Gamma \left(m + \frac{1}{2} \right) \Gamma \left(n + \frac{1}{2} \right) \int_0^{\infty} \left[(v^2 - 1)^{-1/2} - (v^2 - 1)^{1/2} \right] v^{-(m+n)} J_{m+\frac{1}{2}}(kdv) J_{n+\frac{1}{2}}(kdv) dv. \quad (3.43)$$

¹See reference [30], p. 373.

If we define $F_{mn}(\alpha)$ as

$$F_{mn}(\alpha) = \int_0^\infty (v^2 - 1)^{1/2} v^{-(m+n)} J_{m+\frac{1}{2}}(\alpha v) J_{n+\frac{1}{2}}(\alpha v) dv, \quad (3.44)$$

it can be shown that

$$C_{mn} = \frac{\pi}{2} \left(\frac{2}{kd} \right)^{m+n} d^3 \Gamma \left(m + \frac{1}{2} \right) \Gamma \left(n + \frac{1}{2} \right) [(m+n-3)F_{mn}(kd) - kdF'_{mn}(kd)], \quad (3.45)$$

where the prime stands for differentiation with respect to the argument. With the substitution of the above into Eq. (3.31) we obtain

$$\mathcal{Z}^{(1)} = j \frac{Z_0}{\pi^2 d^2} (kd) \frac{B_1^2}{F_{11}(kd) + kdF'_{11}(kd)}. \quad (3.46)$$

In order to evaluate the function $F_{mn}(\alpha)$ we divide the integration range into two parts

$$F_{mn}(\alpha) = R_{mn}(\alpha) + jI_{mn}(\alpha), \quad (3.47)$$

where

$$\begin{aligned} I_{mn}(\alpha) &= \int_0^1 (1-v^2)^{1/2} v^{-(m+n)} J_{m+\frac{1}{2}}(\alpha v) J_{n+\frac{1}{2}}(\alpha v) dv, \\ R_{mn}(\alpha) &= \int_1^\infty (v^2-1)^{1/2} v^{-(m+n)} J_{m+\frac{1}{2}}(\alpha v) J_{n+\frac{1}{2}}(\alpha v) dv. \end{aligned} \quad (3.48)$$

For the first few values of m and n Levine and Schwinger [19] found

$$\begin{aligned} I_{11}(\alpha) &= \frac{\alpha}{2\pi} - \frac{1}{4\pi\alpha} + \frac{1}{8\alpha^2} S_0(2\alpha) - \frac{1}{16\alpha^3} \int_0^{2\alpha} S_0(t) dt - \frac{1}{4\alpha} \int_0^{2\alpha} \frac{S_1(t)}{t} dt, \\ R_{11}(\alpha) &= \frac{1}{4\alpha} \left(1 + \frac{1}{4\alpha^2} \right) \int_0^{2\alpha} J_0(t) dt - \frac{1}{8\alpha^2} J_0(2\alpha) - \frac{1}{4\alpha} J_1(2\alpha), \end{aligned} \quad (3.49)$$

where S_0 and S_1 denote the zeroth- and first-order Struve functions respectively. The similarity between the two functions may be illustrated by

comparing the integral representation of the two functions

$$\begin{aligned} S_\nu(z) &= \frac{2(z/2)^\nu}{\Gamma(\nu + \frac{1}{2})\Gamma(\frac{1}{2})} \int_0^1 (1-t^2)^{\nu-\frac{1}{2}} \sin zt dt, \\ J_\nu(z) &= \frac{2(z/2)^\nu}{\Gamma(\nu + \frac{1}{2})\Gamma(\frac{1}{2})} \int_0^1 (1-t^2)^{\nu-\frac{1}{2}} \cos zt dt. \end{aligned}$$

We now need to calculate B_n in order to obtain the complete expression for the impedance. In the plane of the hole $y=0$ the source fields become

$$H_x = -\frac{I_0}{\pi} \frac{b}{x^2 + b^2} e^{-jkz}, \quad H_z = 0. \quad (3.50)$$

Thus

$$\begin{aligned} B_n &= \int \mathbf{H}^i \cdot (\mathbf{E} \times \mathbf{n}) dS, \\ &= -\frac{b}{\pi} \int_{S_a} \left(1 - \frac{\rho^2}{d^2}\right)^{n-\frac{1}{2}} \frac{e^{-jkz}}{x^2 + b^2} dS. \end{aligned} \quad (3.51)$$

Assuming that the source current is far from the hole i.e. $\Gamma x/b \ll 1$ and assuming that the field is static B_n becomes

$$B_n = \frac{2\pi d^2}{(2n+1)} H_0 = -\frac{2d^2}{(2n+1)b}.$$

In fact this is the approximation on which Bethe's small hole theory is based. Later we will factor this quantity out of a whole expression leaving the effect of finite size of the hole and the effect of phase variation along the hole in the compact form. We will call this a form factor.

For general cases introducing the change of the variables $z = \rho \cos \theta$ and $x = \rho \sin \theta$ and denoting $w = \rho/b$ we find from Eq. (3.51)

$$B_n = 2H_0 \int_0^d \left(1 - \frac{\rho^2}{d^2}\right)^{n-\frac{1}{2}} \rho d\rho \int_0^\pi \frac{e^{-jkbw \cos \theta}}{w^2 \sin^2 \theta + 1} d\theta. \quad (3.52)$$

We integrate the second term to obtain

$$\begin{aligned} \int_0^\pi \frac{e^{-jkbw \cos \theta}}{w^2 \sin^2 \theta + 1} d\theta &= \sum_{m=0}^{\infty} (-1)^m w^{2m} \int_0^\pi e^{-jkbw \cos \theta} \sin^{2m} \theta d\theta \\ &= \sum_{m=0}^{\infty} (-1)^m \frac{2^m \rho^m}{b^{2m} k^m} \Gamma\left(m + \frac{1}{2}\right) \Gamma\left(\frac{1}{2}\right) J_m(k\rho). \end{aligned}$$

Substituting the above into Eq. (3.52) and using

$$\begin{aligned} \int_0^d \left(1 - \frac{\rho^2}{d^2}\right)^{n-\frac{1}{2}} \rho^{m+1} J_m(k\rho) d\rho &= d^{m+2} \int_0^{\frac{\pi}{2}} J_m(kd \sin \theta) \cos^{2n} \theta \sin^{m+1} \theta d\theta \\ &= d^{m+2} \frac{2^{n-\frac{1}{2}} \Gamma(n + \frac{1}{2})}{(kd)^{n+\frac{1}{2}}} J_{m+n+\frac{1}{2}}(kd), \end{aligned}$$

we may rewrite B_n as

$$B_n = \frac{2\pi d^2}{2n+1} H_0 FF_n\left(\frac{d}{b}, kd\right), \quad (3.53)$$

$$\begin{aligned} FF_n\left(\frac{d}{b}, kd\right) &= \sqrt{\frac{\pi}{2}} (2n+1)!! \cdot \\ &\left[\frac{J_{n+\frac{1}{2}}(kd)}{(kd)^{n+\frac{1}{2}}} + \sum_1^{\infty} (-1)^m (2m-1)!! \left(\frac{d}{b}\right)^{2m} \frac{J_{m+n+\frac{1}{2}}(kd)}{(kd)^{m+n+\frac{1}{2}}} \right], \end{aligned} \quad (3.54)$$

where $FF_n(\frac{d}{b}, kd)$ denotes ‘‘form factor’’ mentioned before. We can verify that

$$FF_n\left(\frac{d}{b}, kd\right) \simeq 1 \text{ as } kd \rightarrow 0 \text{ and } \frac{d}{b} \rightarrow 0,$$

$$FF_n\left(\frac{d}{b}, ka\right) \simeq (kd)^{-n-1} \text{ as } kd \rightarrow \infty \text{ and } \frac{d}{b} < 1.$$

The series in the form factor is uniformly convergent in the whole range of kd if $d/b < 1$. The fast convergence of series can be seen in Fig. 3.2 which shows that even the first term alone is a very good approximation. The first term contribution arises from the phase variation along the hole with the source current being far from the hole. The amplitude of the source field is constant in the hole and is equal to the

value at the center of the hole. We may approximate the form factor as

$$FF_n(kd) \simeq \sqrt{\frac{\pi}{2}}(2n+1)!! \frac{J_{n+\frac{1}{2}}(kd)}{(kd)^{n+\frac{1}{2}}}. \quad (3.55)$$

We now express $\mathcal{Z}^{(1)}$ in a form which is convenient for numerical evaluation

$$\mathcal{Z}^{(1)} = j \frac{4Z_0 d^2 H_0^2}{9} (kd) \frac{FF_1^2}{F_{11}(kd) + kdF'_{11}(kd)}. \quad (3.56)$$

Numerical values of $\mathcal{Z}^{(1)}$ can be obtained by substituting Eqs. (3.49) and (3.53) into Eq. (3.56). Since all the functions used in the expression are tabulated in standard reference materials it is easy to do; the result is shown in Fig. 3.3.

From the figure we observe that the resonance frequency k_r occurs at $kd = 1.6$ where $Im Z(k)$ is equal to zero by definition. Since all the electromagnetic power is dissipated at the resonance $Re Z(k)$ must have a maximum value there. But the figure shows that the maximum of $Re Z(k)$ occurs at $kd = 1.3$ which contradicts physical argument. Such an unphysical phenomenon may be corrected if we include the tangential field due to the incident electric field in Bethe's solution in our trial fields.

In order to investigate the impedance in the low frequency range we use the expansions [19]

$$\begin{aligned} I_{11}(\alpha) &= \frac{2\alpha^3}{27\pi} - \frac{4\alpha^5}{675\pi} + \frac{16\alpha^7}{55125\pi} - \dots, \\ R_{11}(\alpha) &= \frac{1}{3} - \frac{\alpha^2}{15} + \frac{\alpha^4}{140} - \dots. \end{aligned}$$

We may write the impedance functional in a form appropriate to small values of kd :

$$Re \mathcal{Z}^{(1)} = \frac{32Z_0 d^2 H_0^2}{27\pi} (kd)^4 \left(1 + \frac{22}{25}(kd)^2 - \dots \right), \quad (3.57)$$

$$Im \mathcal{Z}^{(1)} = \frac{4Z_0 d^2 H_0^2}{3} (kd) \left(1 + \frac{2}{5}(kd)^2 - \dots \right). \quad (3.58)$$

If we compare these with the low frequency result $Z(k) = j(2Z_0d^3H_0^2/3)kd$ we find that the result from the variational method is a factor of two larger than the low frequency result. This may be explained again by the fact that we excluded the tangential field in the hole due to the electric field in our trial fields.

Since the impedance shown in Fig. 3.3 is similar to the impedance of a parallel RLC-resonator circuit it would be useful if we described our impedance functional in terms of circuit parameters. The impedance of a broadband RLC-resonator circuit is

$$Z_{bb}(\omega) = \frac{R}{1 + jQ\left(\frac{\omega}{\omega_r} - \frac{\omega_r}{\omega}\right)}, \quad (3.59)$$

where Q is the quality factor and ω_r is the resonant frequency. In the limit of low frequency

$$Z_{bb}(\omega) \simeq jR(\omega/\omega_r)/Q. \quad (3.60)$$

The quality factor Q is defined by

$$Q = \frac{\omega_r}{2\Delta\omega}, \quad (3.61)$$

where $|Z_{bb}(\omega)|$ at the frequency $\omega = \omega_r + \Delta\omega$ is 0.707 of its maximum value.

From the above definition we find that

$$\omega_r \cong \frac{1.6c}{d}, \quad Q \cong 1.8, \quad R \cong 3.84Z_0d^2H_0^2. \quad (3.62)$$

The second-order variational solution of impedance $\mathcal{Z}^{(2)}$ can be written as

$$\mathcal{Z}^{(2)} = j\frac{4Z_0d^2H_0^2}{9}(kd) \frac{(F_{22} - kdF'_{22})FF_1^2 - \frac{k^2d^2}{25}[(F_{11} + kdF'_{11})FF_2^2 - 10F'_{12}FF_1FF_2]}{(F_{11} + kdF'_{11})(F_{22} - kdF'_{22}) + (kdF'_{12})^2}. \quad (3.63)$$

Numerical values of $\mathcal{Z}^{(2)}$ are shown in Fig. 3.4. The same comments as in Fig. 3.3 apply here also.

In conclusion we have derived the formula for the coupling impedance of a hole in an infinite screen based on a variational method. Our results show that the hole is acting like a broadband resonator circuit and our formulas are suitable for determining the circuit parameters which are of practical use. However in using one type of trial field it is shown that the resulting impedance exhibits unphysical behavior. Such a deficiency of the method is not removed by simply going to the higher order approximation. We therefore believe that in order to obtain physically consistent results we should include another type of trial field namely the field inside the hole due to the electric field which appeared in Bethe's low frequency solution. This is carried out in the next section.

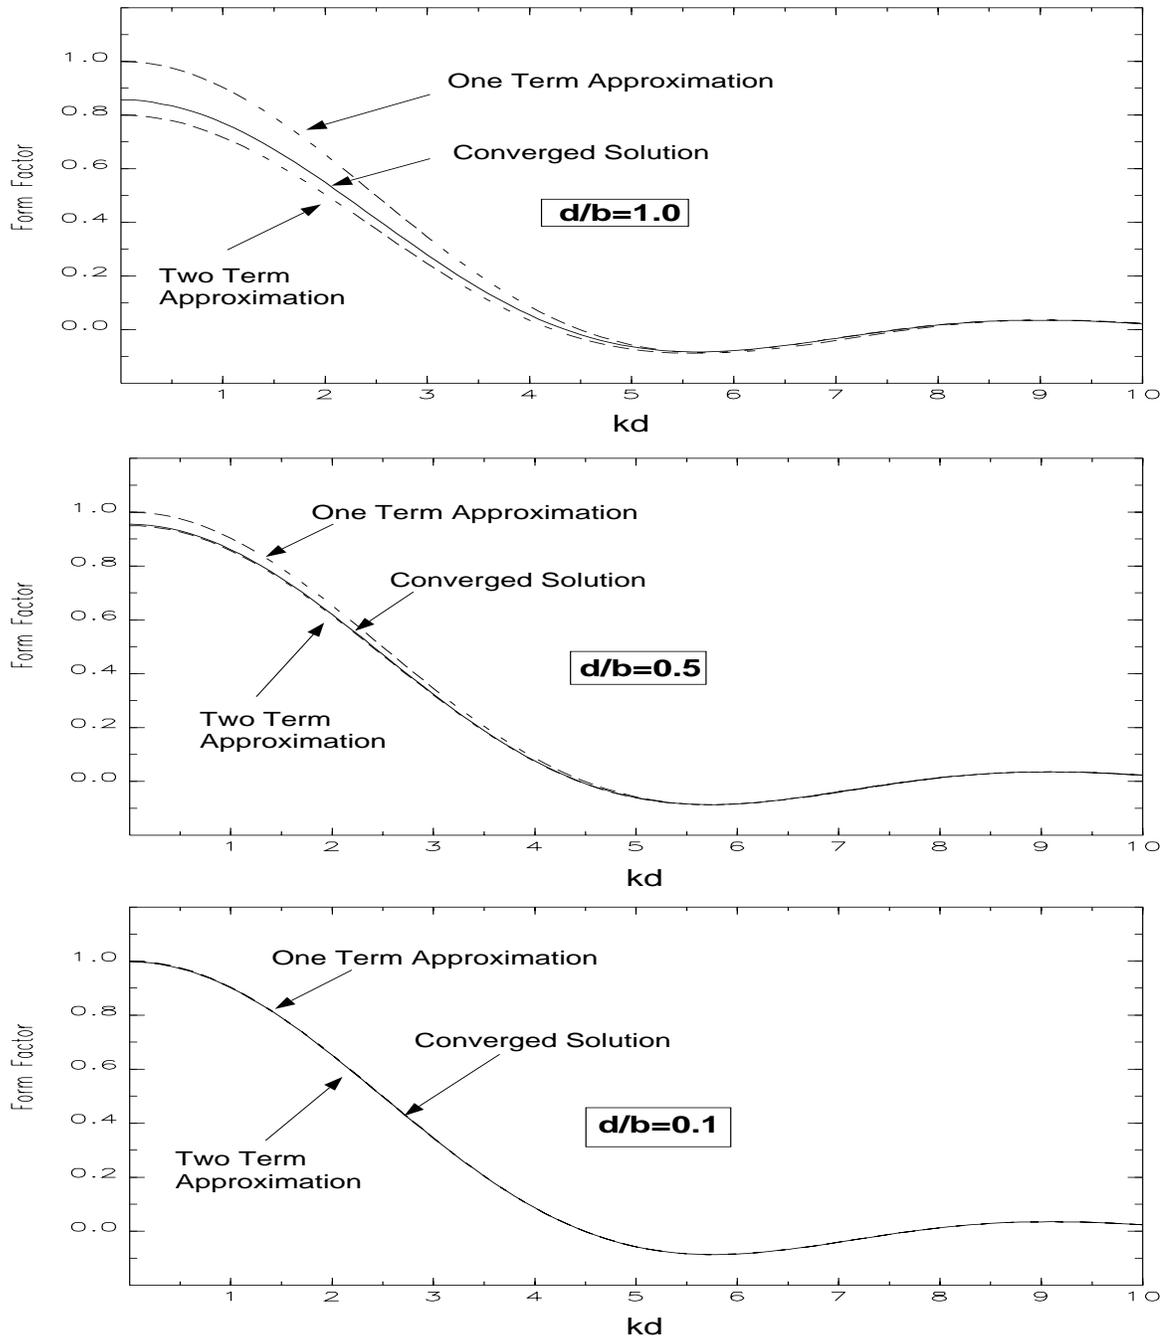

Figure 3.2: Form factor as functions of kd .

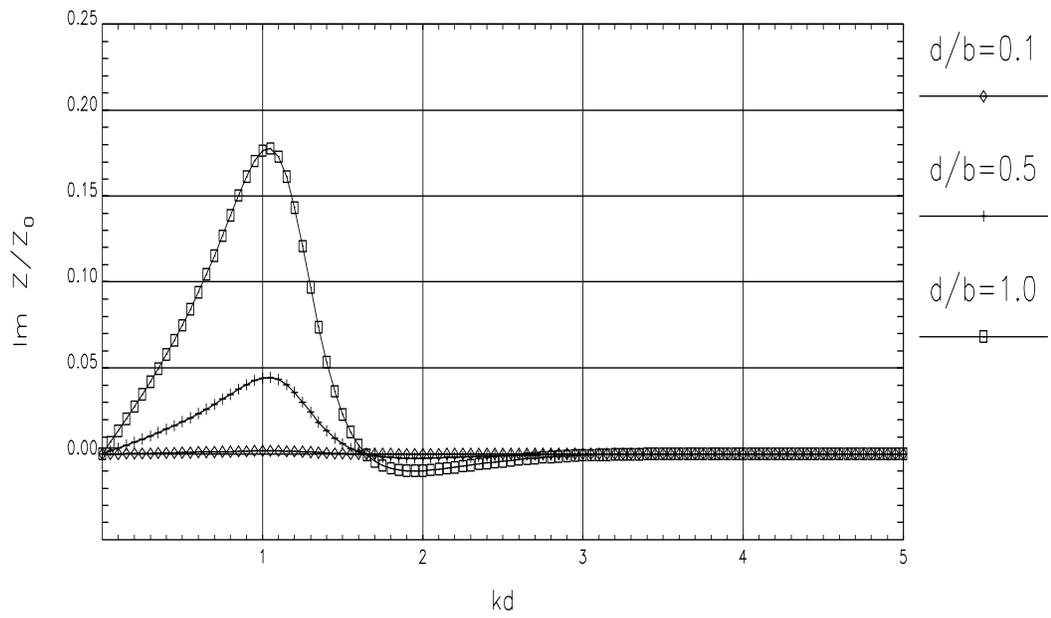

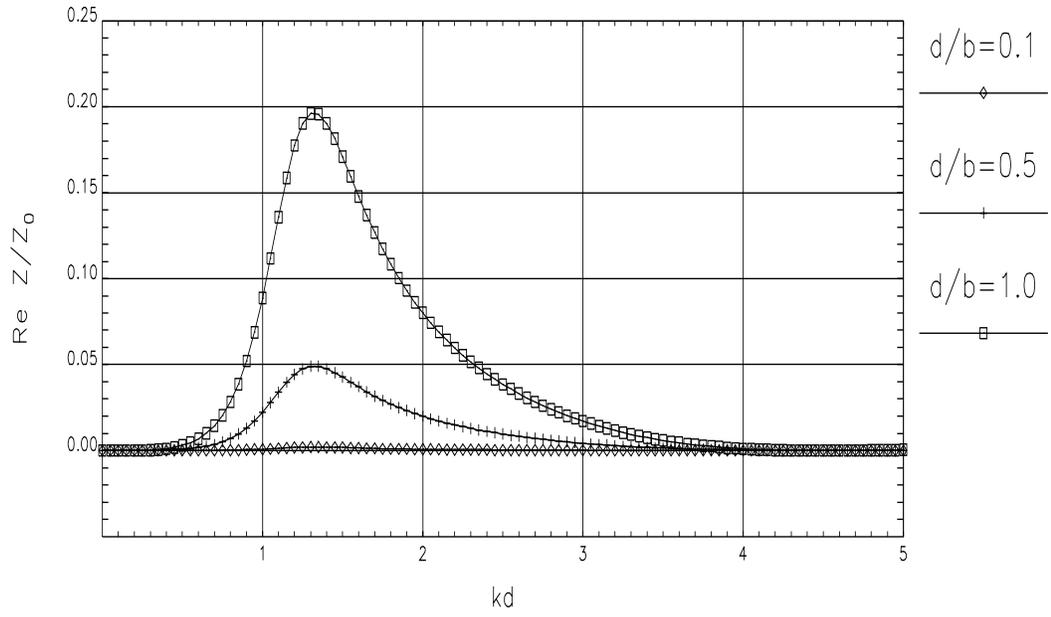

Figure 3.3: Impedance Functional $\mathcal{Z}^{(1)}(kd)$ for various d/b values.

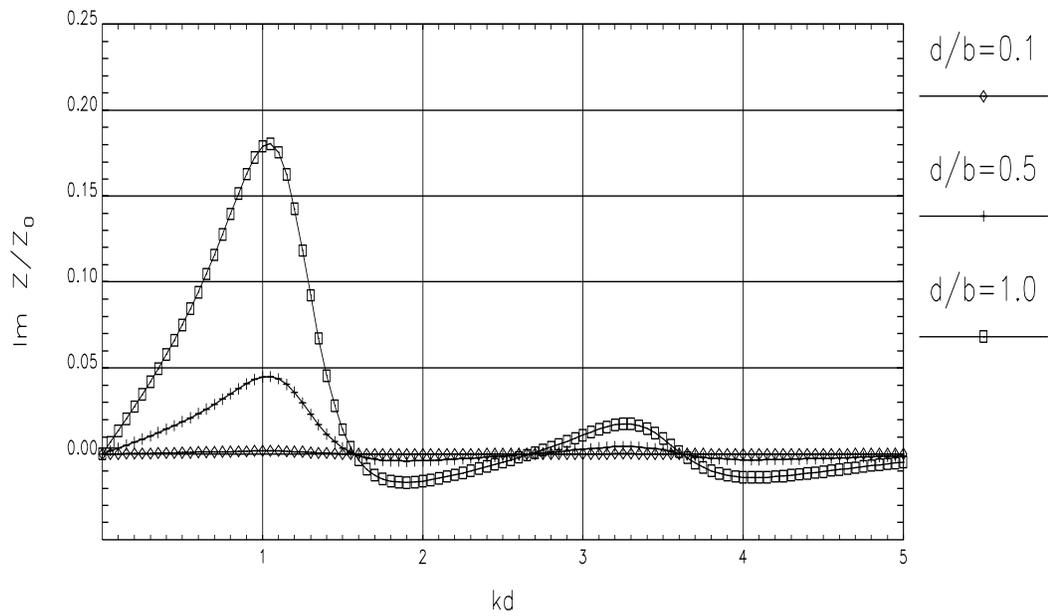

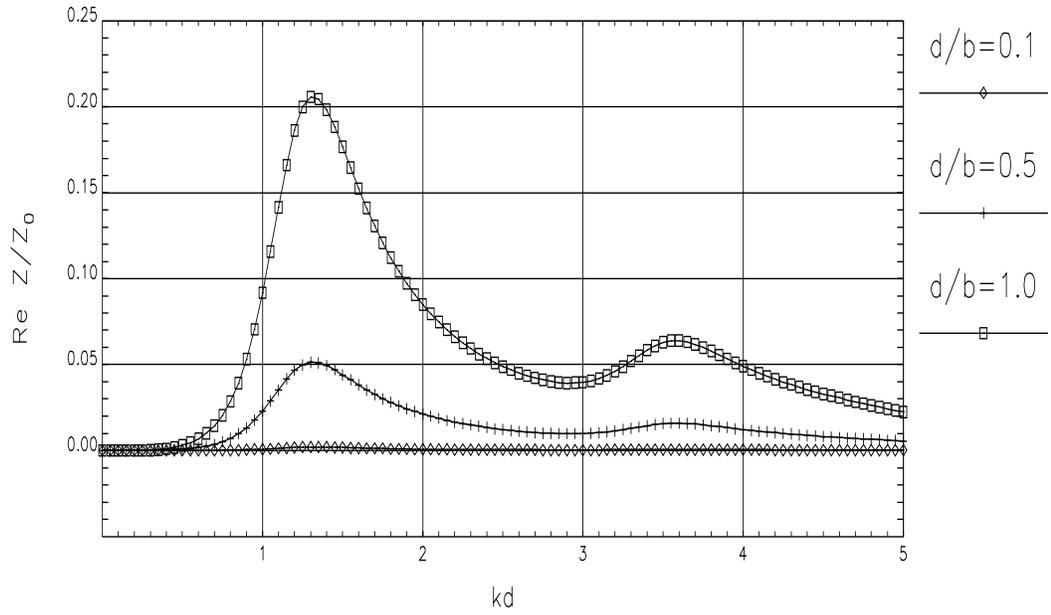

Figure 3.4: Impedance Functional $\mathcal{Z}^{(2)}(kd)$ for various d/b values.

3.3.3 The Second Variational Solution

In order to eliminate the unphysical behavior of the longitudinal coupling impedance found in the previous section we include the tangential field in the hole due to the incident electric field in our variational calculation. An appropriate two-component trial field in the hole based on Bethe's solution is taken to be

$$\mathbf{n} \times \mathbf{E} = a_1 \sqrt{1 - (\rho/d)^2} \mathbf{e}_x + b_1 \frac{(\rho/d)}{\sqrt{1 - (\rho/d)^2}} \mathbf{e}_\theta. \quad (3.64)$$

Since the impedance functional $\mathcal{Z}(k)$ is

$$\mathcal{Z}(k) = \frac{1}{4j\omega\epsilon} \frac{\left[\int_{S_a} \mathbf{H}^i \cdot (\mathbf{n} \times \mathbf{E}) dS \right]^2}{\int_{S_a} \int_{S_a} [\mathbf{n} \times \mathbf{E}(\mathbf{r})] \cdot \overline{\mathbf{G}}_0(\mathbf{r}|\mathbf{r}') \cdot [\mathbf{n} \times \mathbf{E}(\mathbf{r}')] dS dS'}, \quad (3.65)$$

we may write the numerator as

$$\left(a_1 B_1^a + b_1 B_1^b \right)^2, \quad (3.66)$$

and the denominator as

$$4j\omega\epsilon \left[a_1^2 C_{11}^{aa} + a_1 b_1 C_{11}^{ab} + b_1^2 C_{11}^{bb} \right], \quad (3.67)$$

where

$$\begin{aligned} B_1^a &= \int_{S_a} H_x^i(\rho, \theta) \sqrt{1 - (\rho/d)^2} dS, \\ B_1^b &= \int_{S_a} H_x^i(\rho, \theta) \frac{(\rho/d)}{\sqrt{1 - (\rho/d)^2}} dS, \\ C_{11}^{aa} &= \int_0^d \sqrt{1 - (\rho/d)^2} \rho d\rho \int_0^d \sqrt{1 - (\rho'/d)^2} \rho' d\rho' \int_0^{2\pi} d\theta \int_0^{2\pi} d\theta' \\ &\quad [\sin \theta \sin \theta' G_{\rho\rho'} + \sin \theta \cos \theta' G_{\rho\theta'} + \cos \theta \sin \theta' G_{\theta\rho'} + \cos \theta \cos \theta' G_{\theta\theta'}], \end{aligned}$$

$$\begin{aligned}
C_{11}^{ab} &= \int_0^d \sqrt{1 - (\rho/d)^2} \rho d\rho \int_0^d \frac{(\rho'/d)}{\sqrt{1 - (\rho'/d)^2}} \rho' d\rho' \\
&\quad \int_0^{2\pi} d\theta \int_0^{2\pi} d\theta' [\sin \theta G_{\rho\theta'} + \cos \theta G_{\theta\theta'}] \\
&+ \int_0^d \sqrt{1 - (\rho'/d)^2} \rho' d\rho' \int_0^d \frac{(\rho/d)}{\sqrt{1 - (\rho/d)^2}} \rho d\rho \\
&\quad \int_0^{2\pi} d\theta \int_0^{2\pi} d\theta' [\sin \theta' G_{\theta\rho'} + \cos \theta' G_{\theta\theta'}], \\
C_{11}^{bb} &= \int_0^d \frac{(\rho/d)}{\sqrt{1 - (\rho/d)^2}} \rho d\rho \int_0^d \frac{(\rho'/d)}{\sqrt{1 - (\rho'/d)^2}} \rho' d\rho' \int_0^{2\pi} d\theta \int_0^{2\pi} d\theta' G_{\theta\theta'}.
\end{aligned}$$

The components of dyadic Green's function in the cylindrical coordinate system are defined by

$$\begin{aligned}
G_{\rho\rho'} &= \left(\cos(\theta - \theta') - \frac{1}{k^2} \frac{\partial^2}{\partial \rho \partial \rho'} \right) G, \\
G_{\rho\theta'} &= \left(\sin(\theta - \theta') - \frac{1}{k^2 \rho'} \frac{\partial^2}{\partial \rho \partial \theta'} \right) G, \\
G_{\theta\rho'} &= \left(-\sin(\theta - \theta') - \frac{1}{k^2 \rho} \frac{\partial^2}{\partial \theta \partial \rho'} \right) G, \\
G_{\theta\theta'} &= \left(\cos(\theta - \theta') - \frac{1}{k^2 \rho \rho'} \frac{\partial^2}{\partial \theta \partial \theta'} \right) G,
\end{aligned}$$

where G is the free-space scalar Green's function which can be expressed as

$$\begin{aligned}
G &= \frac{e^{-jkR}}{4\pi R} = \frac{1}{4\pi} \int_0^\infty \frac{q dq}{\sqrt{q^2 - k^2}} J_0(qR) \\
&= \frac{1}{4\pi} \sum_0^\infty (2 - \delta_{0n}) \cos n(\theta - \theta') \int_0^\infty \frac{q dq}{\sqrt{q^2 - k^2}} J_n(q\rho) J_n(q\rho').
\end{aligned}$$

The impedance functional Γ in terms of these coefficients Γ may be written as

$$\mathcal{Z}(k) = \frac{(a_1 B_1^a + b_1 B_1^b)^2}{4j\omega\epsilon [a_1^2 C_{11}^{aa} + a_1 b_1 C_{11}^{ab} + b_1^2 C_{11}^{bb}]}, \quad (3.68)$$

or

$$4j\omega\epsilon [a_1^2 C_{11}^{aa} + a_1 b_1 C_{11}^{ab} + b_1^2 C_{11}^{bb}] \mathcal{Z}(k) = (a_1 B_1^a + b_1 B_1^b)^2. \quad (3.69)$$

A stationary property of $\mathcal{Z}\Gamma$, i.e. $\Gamma \partial \mathcal{Z} / \partial a_1 = 0$ yields

$$2a_1 C_{11}^{aa} + b_1 C_{11}^{ab} = -j \frac{Z_0}{2k} B_1^a, \quad (3.70)$$

and Γ similarly from $\partial \mathcal{Z} / \partial b_1 = 0$ we have

$$a_1 C_{11}^{ab} + 2b_1 C_{11}^{bb} = -j \frac{Z_0}{2k} B_1^b. \quad (3.71)$$

Solving two linear algebraic equations Γ we obtain

$$a_1 = j \frac{Z_0}{2k} \frac{C_{11}^{ab} B_1^b - 2C_{11}^{bb} B_1^a}{4C_{11}^{aa} C_{11}^{bb} - (C_{11}^{ab})^2}, \quad (3.72)$$

$$b_1 = j \frac{Z_0}{2k} \frac{C_{11}^{ab} B_1^a - 2C_{11}^{aa} B_1^b}{4C_{11}^{aa} C_{11}^{bb} - (C_{11}^{ab})^2}. \quad (3.73)$$

Once the unknown coefficients $a_1(k)$ and $b_1(k)$ are determined Γ the impedance functional can be calculated from the definition

$$\mathcal{Z}(k) = a_1 B_1^a + b_1 B_1^b. \quad (3.74)$$

We can also calculate the longitudinal coupling impedance which may be written as

$$Z(k) = a_1 B_1^{a*} + b_1 B_1^{b*}. \quad (3.75)$$

We first evaluate C_{11}^{bb} . The corresponding integral in angle variables becomes

$$\begin{aligned} \int_0^{2\pi} \int_0^{2\pi} d\theta d\theta' G_{\theta\theta'} &= \frac{1}{4\pi} \left[\int_0^{2\pi} \int_0^{2\pi} d\theta d\theta' \cos(\theta - \theta') \sum_0^{\infty} (2 - \delta_{0n}) \cos n(\theta - \theta') \right. \\ &\quad \left. - \int_0^{2\pi} \int_0^{2\pi} d\theta d\theta' \frac{1}{k^2 \rho \rho'} \frac{\partial^2}{\partial \theta \partial \theta'} \sum_0^{\infty} (2 - \delta_{0n}) \cos n(\theta - \theta') \right] \\ &\quad \int_0^{\infty} \frac{q dq}{\sqrt{q^2 - k^2}} J_1(q\rho) J_1(q\rho'). \end{aligned}$$

From the orthogonal property of trigonometric functions we get

$$\int_0^{2\pi} \int_0^{2\pi} d\theta d\theta' G_{\theta\theta'} = \pi \int_0^{\infty} \frac{q dq}{\sqrt{q^2 - k^2}} J_1(q\rho) J_1(q\rho'). \quad (3.76)$$

If we define

$$I_1^b = \int_0^d \frac{(\rho/d)}{\sqrt{1 - (\rho/d)^2}} J_1(q\rho) \rho d\rho, \quad (3.77)$$

we have

$$C_{11}^{bb} = \pi \int_0^{\infty} \frac{q dq}{\sqrt{q^2 - k^2}} I_1^b I_1^b. \quad (3.78)$$

A similar procedure yields

$$C_{11}^{ab} = 0, \quad (3.79)$$

$$C_{11}^{aa} = \frac{\pi}{2} \int_0^{\infty} \frac{q dq}{\sqrt{q^2 - k^2}} \left[I_0^a I_0^a + I_2^a I_2^a - \frac{q^2}{k^2} I_0^a I_0^a \right], \quad (3.80)$$

where I_0^a and I_2^a are defined by

$$I_0^a = \int_0^d \sqrt{1 - \left(\frac{\rho}{d}\right)^2} J_0(q\rho) \rho d\rho, \quad (3.81)$$

$$I_2^a = \int_0^d \sqrt{1 - \left(\frac{\rho}{d}\right)^2} J_2(q\rho) \rho d\rho. \quad (3.82)$$

Since $C_{11}^{ab} = 0$ the unknown coefficients a_1 and b_1 are simplified to

$$a_1 = -j \frac{Z_0}{4k} \frac{B_1^a}{C_{11}^{aa}}, \quad b_1 = -j \frac{Z_0}{4k} \frac{B_1^b}{C_{11}^{bb}}. \quad (3.83)$$

We further note that

$$4j\omega\epsilon a_1^2 C_{11}^{aa} = 4j\omega\epsilon \int_{S_a} \int_{S_a} \left(a_1 \sqrt{1 - (\rho/d)^2} \right) G_{xx}(\rho, \theta | \rho', \theta') \left(a_1 \sqrt{1 - (\rho'/d)^2} \right) dS dS' \quad (3.84)$$

which indicates that

$$C_{11}^{aa} = C_{11}/2, \quad (3.85)$$

where C_{11} is defined in Eq. (3.26) Section 3.3.2. We also note that B_1^a is equal to B_1 defined in Eq. (3.25) Section 3.3.2. Thus we only need to evaluate C_{11}^{bb} and B_1^b .

Before we carry out the necessary integrals for C_{11}^{bb} we note that if we define

$$Z_H(k) = a_1 B_1^{a*} = -j \frac{Z_0 |B_1^a|^2}{4k C_{11}^{aa}} = -j \frac{Z_0 |B_1|^2}{2k C_{11}}, \quad (3.86)$$

$$Z_E(k) = b_1 B_1^{b*} = -j \frac{Z_0 |B_1^b|^2}{4k C_{11}^{bb}}, \quad (3.87)$$

$Z(k)$ can be written as

$$Z(k) = Z_E(k) + Z_H(k), \quad (3.88)$$

where $Z_H(k)$ is already calculated in Section 3.3.2. From this we find that the tangential fields in the hole due to electric field and magnetic field contribute to the impedance separately.

In order to show the order of approximation we adopt the following notation

$$Z^{(N+M)} = Z_E^{(N)} + Z_H^{(M)}, \quad (3.89)$$

where M or N denotes the order of approximation or the number of terms used for the trial field and $Z_H^{(N)} = Z_H^{(N)}$ is calculated in Section 3.3.2.

Using Sonine's first finite integral formula we evaluate I_1^b as follows

$$I_1^b = \int_0^d \frac{(\rho/d)}{\sqrt{1 - (\rho^2/d^2)}} J_1(q\rho) \rho d\rho$$

$$\begin{aligned}
&= d^2 \int_0^{\pi/2} J_1(qd \sin \theta) \sin^2 \theta d\theta \\
&= d^2 \sqrt{\frac{\pi}{2}} \frac{J_{3/2}(qd)}{(qd)^{1/2}}.
\end{aligned}$$

Substituting the above into Eq. (3.78) we obtain

$$C_{11}^{bb} = \frac{\pi^2 d^3}{2} \int_0^\infty \frac{J_{3/2}^2(qd)}{\sqrt{q^2 - k^2}} dq. \quad (3.90)$$

Introducing a new variable $\alpha = kd$ we separate the above into two parts that is

$$C_{11}^{bb} = \frac{\pi^2 d^3}{2} I = \frac{\pi^2 d^3}{2} (I_1 - I_2), \quad (3.91)$$

where

$$I_1 = \int_0^\infty \frac{J_{3/2}(q) J_{1/2}(q)}{q \sqrt{q^2 - \alpha^2}} dq, \quad I_2 = \int_0^\infty \frac{J_{3/2}(q) J_{-1/2}(q)}{\sqrt{q^2 - \alpha^2}} dq. \quad (3.92)$$

From the product representation of the Bessel function

$$J_\mu(z) J_\nu(z) = \frac{2}{\pi} \int_0^{\pi/2} J_{\mu+\nu}(2z \cos \theta) \cos(\mu - \nu)\theta d\theta, \quad \text{Re}(\mu + \nu) > -1, \quad (3.93)$$

we find

$$I_1 = \frac{2}{\pi} \int_0^{\pi/2} \cos \theta d\theta \int_0^\infty \frac{J_2(2q \cos \theta)}{q \sqrt{q^2 - \alpha^2}} dq, \quad (3.94)$$

$$I_2 = \frac{2}{\pi} \int_0^{\pi/2} \cos 2\theta d\theta \int_0^\infty \frac{J_1(2q \cos \theta)}{\sqrt{q^2 - \alpha^2}} dq. \quad (3.95)$$

We first consider the real part of I_1 .

$$\begin{aligned}
\text{Re } I_1 &= \frac{2}{\pi} \int_0^{\pi/2} \cos \theta d\theta \int_\alpha^\infty \frac{J_2(2q \cos \theta)}{q \sqrt{q^2 - \alpha^2}} dq, \\
&= \frac{2}{\pi} \int_0^{\pi/2} \cos \theta d\theta \sqrt{\frac{\pi}{2}} \frac{J_{3/2}(2\alpha \cos \theta)}{(2 \cos \theta)^{1/2} \alpha^{3/2}},
\end{aligned}$$

where we used the integral formula²

$$\begin{aligned}
\int_x^\infty \frac{J_\nu(ax)}{x^{\nu-1}} (x^2 - z^2)^\mu dx &= \frac{2^\mu \Gamma(\mu + 1)}{a^{\mu+1} z^{\nu-\mu-1}} J_{\nu-\mu-1}(az), \\
a &\geq 0, \quad \text{Re} \left(\frac{\nu}{2} - \frac{1}{4} \right) > \text{Re} \mu > -1. \quad (3.96)
\end{aligned}$$

²See reference [30], p. 417.

When ν is half of an odd integer Γ the function $J_\nu(z)$ has a finite representation in terms of algebraic and trigonometric functions of z *i.e.* Γ

$$J_{3/2}(z) = \sqrt{\frac{2}{\pi z}} \left(\frac{\sin z}{z} - \cos z \right). \quad (3.97)$$

Then

$$Re I_1 = \frac{1}{\pi \alpha^2} \int_0^{\pi/2} d\theta \left[\frac{\sin(2\alpha \cos \theta)}{2\alpha \cos \theta} - \cos(2\alpha \cos \theta) \right]. \quad (3.98)$$

If we define

$$F_1(\alpha) = \int_0^{\pi/2} \frac{\sin(2\alpha \cos \theta)}{2 \cos \theta} d\theta, \quad (3.99)$$

we find

$$Re I_1 = \frac{1}{\pi \alpha^2} \left[\frac{F_1(\alpha)}{\alpha} - \frac{\pi}{2} J_0(2\alpha) \right]. \quad (3.100)$$

Since

$$F_1'(\alpha) = \int_0^{\pi/2} \cos(2\alpha \cos \theta) d\theta = \frac{\pi}{2} J_0(2\alpha), \quad (3.101)$$

it follows that

$$F_1(\alpha) = \int_0^\alpha F_1'(t) dt = \frac{\pi}{2} \int_0^\alpha J_0(2t) dt = \frac{\pi}{4} \int_0^{2\alpha} J_0(t) dt. \quad (3.102)$$

Thus we finally obtain the finite representation of $Re I_1$ as

$$Re I_1 = \frac{1}{4\alpha^2} \left[\frac{1}{\alpha} \int_0^{2\alpha} J_0(t) dt - 2J_0(2\alpha) \right]. \quad (3.103)$$

We now consider the imaginary part of I_1 .

$$\begin{aligned} Im I_1 &= -\frac{2}{\pi} \int_0^{\pi/2} \cos \theta d\theta \int_0^\alpha \frac{J_2(2q \cos \theta)}{q \sqrt{\alpha^2 - q^2}} dq \\ &= -\frac{2}{\pi} \int_0^{\pi/2} \cos \theta d\theta \int_0^\alpha \frac{J_2(2\alpha \cos \theta \sin \phi)}{\alpha \sin \phi} d\phi \\ &= -\frac{2}{\pi} \int_0^{\pi/2} \cos \theta d\theta \sqrt{\frac{\pi}{2}} \frac{S_{3/2}(2\alpha \cos \theta)}{(2 \cos \theta)^{1/2} \alpha^{3/2}}, \end{aligned}$$

where we used the general Sonine's first finite integral formula³

$$\int_0^{\pi/2} J_\mu(z \sin \theta) \sin^{1-\mu} \theta d\theta = \sqrt{\frac{\pi}{2z}} S_{\mu-\frac{1}{2}}(z). \quad (3.104)$$

$S_\nu(z)$ is Struve's function which has a finite representation if ν is half of an odd integer i.e.

$$S_{3/2}(z) = \sqrt{\frac{z}{2\pi}} \left(1 + \frac{2}{z^2} - \frac{2}{z} \sin z - \frac{2 \cos z}{z^2} \right). \quad (3.105)$$

With the substitution of a finite representation of Struve's functions we obtain

$$\begin{aligned} \text{Im } I_1 &= -\frac{1}{\pi \alpha^2} \int_0^{\pi/2} d\theta \left[\alpha \cos \theta - \sin(2\alpha \cos \theta) + \frac{1 - \cos(2\alpha \cos \theta)}{2\alpha \cos \theta} \right], \\ &= -\frac{1}{\pi \alpha^2} \left[\alpha - \frac{\pi}{2} S_0(2\alpha) + \frac{F_2(\alpha)}{\alpha} \right], \end{aligned}$$

where we used

$$\int_0^{\pi/2} \sin(z \cos \theta) \sin^{2\nu} \theta d\theta = \frac{\sqrt{\pi} \Gamma(\nu + \frac{1}{2})}{2(\frac{z}{2})^\nu} S_\nu(z), \quad (3.106)$$

and $F_2(\alpha)$ is defined as

$$F_2(\alpha) = \int_0^{\pi/2} \frac{1 - \cos(2\alpha \cos \theta)}{2 \cos \theta} d\theta. \quad (3.107)$$

It is evident that $F_2(0) = 0$ and that

$$F_2'(\alpha) = \int_0^{\pi/2} \sin(2\alpha \cos \theta) d\theta = \frac{\pi}{2} S_0(2\alpha). \quad (3.108)$$

From these it follows that

$$F_2(\alpha) = \int_0^\alpha F_2'(t) dt = \frac{\pi}{2} \int_0^\alpha S_0(2t) dt = \frac{\pi}{4} \int_0^{2\alpha} S_0(t) dt. \quad (3.109)$$

Accordingly

$$\text{Im } I_1 = -\frac{1}{4\alpha^2} \left[\frac{4}{\pi} \alpha - 2S_0(2\alpha) + \frac{1}{\alpha} \int_0^{2\alpha} S_0(t) dt \right]. \quad (3.110)$$

³See reference [30], p. 374.

Following the similar procedure we obtain a finite representation of I_2 as

$$Re I_2 = \frac{1}{2\alpha} \left[2J_1(2\alpha) - \int_0^{2\alpha} J_0(t) dt \right], \quad (3.111)$$

$$Im I_2 = -\frac{1}{2\alpha} \left[2S_1(2\alpha) - \int_0^{2\alpha} S_0(t) dt \right]. \quad (3.112)$$

$$(3.113)$$

Since $I = I_1 - I_2$ we find that

$$Re I = + \left(\frac{1}{4\alpha^3} + \frac{1}{2\alpha} \right) \int_0^{2\alpha} J_0(t) dt - \frac{J_0(2\alpha)}{2\alpha^2} - \frac{J_1(\alpha)}{\alpha}, \quad (3.114)$$

$$Im I = - \left(\frac{1}{4\alpha^3} + \frac{1}{2\alpha} \right) \int_0^{2\alpha} S_0(t) dt + \frac{S_0(2\alpha)}{2\alpha^2} + \frac{S_1(\alpha)}{\alpha} - \frac{1}{\pi\alpha}. \quad (3.115)$$

Substituting these equations into Eq. (3.91) we obtain the expression for C_{11}^{bb} . For the small values of α we may obtain a series expansion which can be written as

$$I(\alpha) = \frac{1}{3} \left(1 + \frac{\alpha^2}{5} - \frac{9\alpha^4}{140} + \dots \right) - j \frac{4\alpha^3}{27\pi} \left(1 - \frac{4\alpha^2}{25} + \dots \right). \quad (3.116)$$

We now need to calculate B_1^b to complete the expression for the impedance. Assuming $\mathbf{H}^i = H_0 e^{-jkz} \mathbf{e}_x$ where H_0 is the field at the hole center we obtain

$$\begin{aligned} B_1^b &= H_0 \int_0^d \rho d\rho \int_0^{2\pi} d\theta \frac{(\rho/d)}{\sqrt{1 - (\rho/d)^2}} \cos \theta e^{-jk\rho \cos \theta} \\ &= -j2\pi H_0 \int_0^d \frac{(\rho/d)}{\sqrt{1 - (\rho/d)^2}} J_1(k\rho) \rho d\rho \\ &= -j2\pi d^2 H_0 \sqrt{\frac{\pi}{2}} \frac{J_{3/2}(kd)}{(kd)^{1/2}}. \end{aligned}$$

With the substitution of C_{11}^{bb} and B_1^b into the expression for $Z_E^{(1)}$ Eq. (3.87) we find

$$Z_E^{(1)} = -j \frac{Z_0 \pi H_0^2 J_{3/2}^2(kd)}{k^2 I(kd)}. \quad (3.117)$$

It may be interesting to compare $Z_E^{(1)}(k)$ and $Z_H^{(1)}$ expanded in powers of kd . We find that

$$\begin{aligned} Z_H^{(1)} &= \frac{32Z_0d^2H_0^2}{27\pi}(kd)^4 \left(1 + \frac{22}{25}(kd)^2 - \dots\right) + j\frac{4Z_0d^2H_0^2}{3}(kd) \left(1 + \frac{2}{5}(kd)^2 - \dots\right), \\ Z_E^{(1)} &= \frac{8Z_0d^2H_0^2}{27\pi}(kd)^4 \left(1 - \frac{19}{25}(kd)^2 + \dots\right) - j\frac{2Z_0d^2H_0^2}{3}(kd) \left(1 - \frac{2}{5}(kd)^2 + \dots\right). \end{aligned}$$

In the low frequency range it is found

$$Z^{(2)} = Z_H^{(1)} + Z_E^{(1)} \simeq j\frac{2Z_0d^3H_0^2}{3}k, \quad (3.118)$$

which is the same as the low frequency result found in Section 3.2.

Numerical results of $Z_H^{(1)}$ and $Z_E^{(1)}$ are presented in Fig. 3.5. There we find that the impedance of magnetic type Z_H is mainly inductive ($Im Z > 0$) and the electric type exhibits capacitive behavior ($Im Z < 0$).

Combining the two effects we have numerical results of $Z^{(2)}(k)$ which are shown in Fig. 3.6. We note that the resonant frequency is located at $kd = 1.35$. We also find that at the resonant frequency the imaginary part of the impedance is zero and the real part has its maximum which is consistent with physical argument. With this new result we revise the circuit parameters Eq. (3.62) found in Section 3.3.2 to the new one

$$\omega_r \cong \frac{1.35c}{d}, \quad Q \cong 1.8, \quad R \cong 1.62Z_0d^2H_0^2. \quad (3.119)$$

When we use the trial field which consists of the three terms

$$\mathbf{n} \times \mathbf{E} = a_1 \left(1 - \frac{\rho^2}{d^2}\right)^{1/2} \mathbf{e}_x + a_2 \left(1 - \frac{\rho^2}{d^2}\right)^{3/2} \mathbf{e}_x + b_1 \frac{(\rho/d)}{\sqrt{1 - (\rho/d)^2}} \mathbf{e}_\theta, \quad (3.120)$$

we have

$$Z^{(3)} = Z_H^{(2)} + Z_E^{(1)}. \quad (3.121)$$

Its numerical values are shown in Fig. 3.7.

In conclusion we have shown that with the inclusion of the tangential field due to the incident electric field in the trial fields the result is consistent with the physical argument.

Chapter 4

Longitudinal Impedance of a Hole in the Accelerator Beam Pipe

4.1 Introduction

In this chapter we evaluate the longitudinal coupling impedance of an aperture in the accelerator beam pipe. Although the beam pipe can have an arbitrary cross-section we assume a beam pipe with a rectangular cross-section which is a good approximation to the elliptical shape used in most of the electron accelerators and storage rings.

Since the aperture connects two regions inside and outside of the beam pipe we need to know the outside geometry to complete the specification of the problem. In a real accelerator the region outside the beam pipe coupled by an aperture is completely arbitrary; it can be a closed vacuum vessel, waveguide structure, transmission line or even a liner structure. Hence in order to understand the fundamental characteristics of an aperture coupling we choose the simplest geometry which has as many symmetries as possible.

These considerations result in the geometry of two equally shaped rectangular

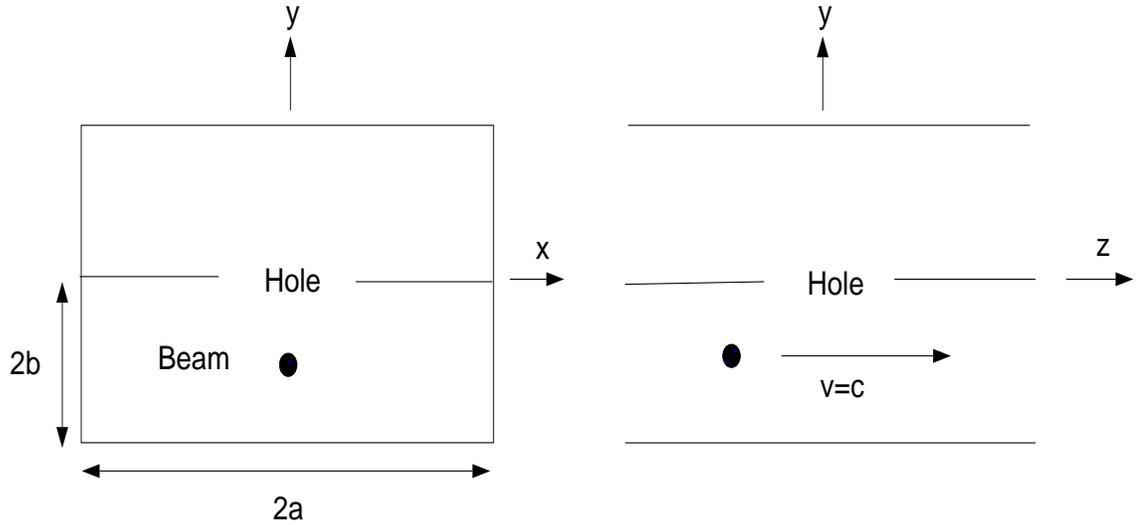

Figure 4.1: Rectangular wave guide coupled by a hole as a model to the accelerator beam pipe with a hole.

waveguides coupled by a hole which is located in the center of the common wall. Such a geometry is shown in Fig. 4.1.

In Section 4.2 we will estimate the impedance in the low frequency range using Bethe's small hole theory.

In Section 4.3 we will obtain the variational solutions of impedance using different trial fields and the results will be compared in Section 4.4 with the numerical calculation from the general wake potential program MAFIA-T3.

4.2 Low Frequency Solution

If the radius of a hole is much smaller than the wavelength and the plane of the hole is the symmetry plane we can use Bethe's result for the field inside hole (see

Eq. (3.2)) which may be written as

$$\mathbf{n} \times \mathbf{E} = -\frac{\rho}{\pi\sqrt{d^2 - \rho^2}} \mathbf{e}_\rho \times \mathbf{E}_0 + j\frac{2kz_0}{\pi}\sqrt{d^2 - \rho^2} \mathbf{H}_0, \quad (4.1)$$

where d is the radius of the hole shown in Fig. 4.1 $\Gamma k = \omega\sqrt{\epsilon_0\mu_0}$ is the free-space wave number Γ and $Z_0 = 377 \Omega$ is the characteristic impedance of free space.

Since we have already obtained a general expression for the impedance in the low frequency range as

$$Z(k) = j\frac{2Z_0d^3H_0^2}{3}k, \quad (4.2)$$

we only need to know the source field $\Gamma H_0 \Gamma$ at the hole center.

The electrostatic potential of line charge of density λ located at $x = x_1, y = y_1$ satisfies the Poisson equation

$$\frac{\partial^2 \Phi}{\partial x^2} + \frac{\partial^2 \Phi}{\partial y^2} = -\frac{\lambda}{\epsilon} \delta(x - x_1) \delta(y - y_1), \quad (4.3)$$

where λ/ϵ can be written in terms of the drive current $\Gamma I_0 \Gamma$ as $\lambda/\epsilon = Z_0 I_0$.

For the rectangular waveguide with walls at $x = \pm a, y = \pm b$ the corresponding Green's function satisfies

$$\frac{\partial^2 G}{\partial x^2} + \frac{\partial^2 G}{\partial y^2} = -\delta(x - x_1) \delta(y - y_1), \quad (4.4)$$

with the boundary condition $G = 0$ at $x = \pm a, y = \pm b$. Expanding Green's function in single series Γ we assume

$$G(x, y) = \sum_1^\infty a_n(y) b_n(x), \quad (4.5)$$

where $a_n(y)$ is the amplitude function and $b_n(x)$ is the basis function which is similar to the Fourier series expansion of an arbitrary function. In a Cartesian coordinate

system we may choose $b_n(x)$ as

$$b_n(x) = \frac{1}{\sqrt{a}} \sin \frac{n\pi}{2a}(x + a) \quad (4.6)$$

which vanishes at $x = \pm a$ and satisfies the orthonormal conditions

$$\int_{-a}^a b_n(x)b_m(x)dx = \delta_{mn}. \quad (4.7)$$

Substituting Eq. (4.5) into Eq. (4.4) we obtain

$$\sum_1^{\infty} \left[\frac{d^2 a_n(y)}{dy^2} - \left(\frac{n\pi}{2a} \right)^2 a_n(y) \right] b_n(x) = -\delta(x - x_1)\delta(y - y_1). \quad (4.8)$$

Multiplying both sides of the equation and integrating we obtain

$$\frac{d^2 a_m(y)}{dy^2} - \left(\frac{m\pi}{2a} \right)^2 a_m(y) = -b_m(x_1)\delta(y - y_1). \quad (4.9)$$

Solving the above equation for $a_m(y)$ by the well-known procedure we find the potential function as

$$\Phi(x, y) = \frac{2I_0 Z_0}{\pi} \sum_{n=1}^{\infty} \frac{\sin \frac{n\pi}{2a}(x + a) \sin \frac{n\pi}{2a}(x_1 + a)}{n \sinh \frac{n\pi b}{a}} \begin{cases} \sinh \frac{n\pi}{2a}(y + b) \sinh \frac{n\pi}{2a}(b - y_1) & y < y_1 \\ \sinh \frac{n\pi}{2a}(b - y) \sinh \frac{n\pi}{2a}(y_1 + b) & y > y_1. \end{cases} \quad (4.10)$$

We note that if we assumed $G = \sum a_n(x)b_n(y)$ we would have an alternative expression with a and b , x and y , x_1 and y_1 interchanged in the above equation.

Using the relation $H_x = -E_y/Z_0$ we obtain H_0 at the center of the hole ($x = 0, y = b, x_1 = y_1 = 0$)

$$H_0 = -\frac{I_0}{2a} \sum_{n=odd} \frac{1}{\cosh \frac{n\pi b}{2a}}. \quad (4.11)$$

This series converges fast. With this we have

$$Z(k) = j \frac{Z_0 d^3}{6a^2} \left(\sum_{n=odd} \frac{1}{\cosh \frac{n\pi b}{2a}} \right)^2 k. \quad (4.12)$$

4.3 Variational Solution

The general expression for impedance in variational method was derived in the previous chapter and was shown to be

$$\mathcal{Z}(k) = -\frac{1}{2} \frac{\left[\int_{S_a} \mathbf{H}^i \cdot (\mathbf{n} \times \mathbf{E}^a) dS \right]^2}{\int_{S_a} \mathbf{H}^a \cdot (\mathbf{n} \times \mathbf{E}^a) dS}, \quad (4.13)$$

where \mathbf{H}^a may be calculated as

$$\mathbf{H}^a(\mathbf{r}) = -j\omega\epsilon \int_{S_a} \overline{\mathbf{G}}_m(\mathbf{r}|\mathbf{r}') \cdot (\mathbf{n} \times \mathbf{E}^a) dS'. \quad (4.14)$$

The dyadic Green's function $\overline{\mathbf{G}}_m$ is of magnetic type whose boundary condition should satisfy $\mathbf{n} \times \nabla \times \overline{\mathbf{G}}_m = 0$ on the walls. The eigenfunction expansion of dyadic Green's function for a rectangular waveguide is developed by Tai [29]. He shows that $\overline{\mathbf{G}}_m$ can be expanded as a double-infinite series of harmonic functions in Cartesian coordinates (x, y, z) . Since the convergence of a series of harmonic functions is very slow and the Cartesian coordinate system suitable for the rectangular waveguide is not convenient in describing a hole in the wall, we use the image principle to remove the guide walls, enabling us to use the familiar free-space dyadic Green's function.

Such a conversion of the geometry from a hole in a waveguide to infinite image holes embedded in free-space is shown in Fig. 4.2. In the original problem, the center of an equivalent magnetic surface current (replacing the hole closed by the conducting wall) is located at the origin inside the waveguide. In the converted problem, waveguide walls are replaced by an infinite array of image magnetic surface currents ("image-source") located at $x = \pm 2na$, $n = 1, 2, 3, \dots$ and $y = \pm 4mb$, $m = 1, 2, 3, \dots$ in addition to the original magnetic surface current ("self-source").

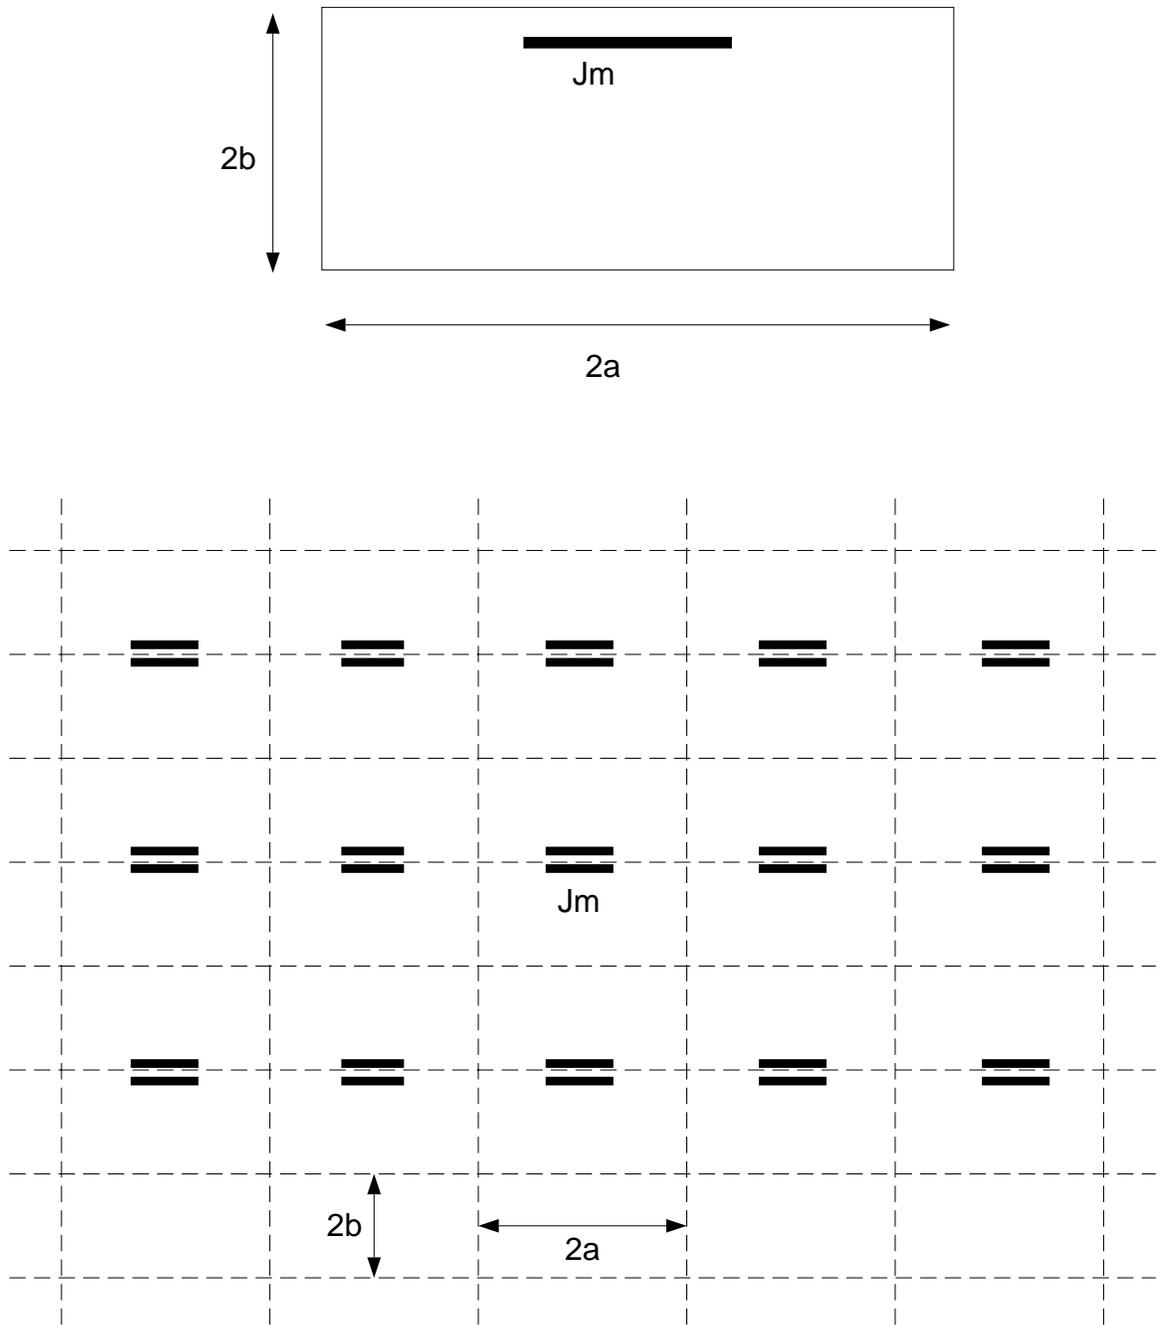

Figure 4.2: Hole in waveguide fits equivalent magnetic surface current and its images in infinite space.

Since we have two contributions to \mathbf{H}^a from the self- and image-sources Γ we separate \mathbf{H}^a into two parts Γ namely Γ

$$\mathbf{H}^a = \mathbf{H}_{self}^a + \mathbf{H}_{image}^a. \quad (4.15)$$

We note that Γ if the contribution from images is zero Γ the impedance functional $\mathcal{Z}(k)$ is the same as the one for a hole in an infinite screen. The only difference is that the source field of the driving beam must be evaluated for waveguide structure. Thus Γ we calculate the contribution from the image-source and compare it with the contribution from the self-source.

For this purpose Γ we use a simple trial field used in Section 3.3.2 which is rewritten as

$$\mathbf{J}_m = \mathbf{n} \times \mathbf{E} = \phi(\rho) \mathbf{e}_x, \quad \phi(\rho) = \sqrt{1 - \frac{\rho^2}{d^2}}. \quad (4.16)$$

If we define the denominator in Eq. (4.13) as

$$D = \int_{S_a} (\mathbf{H}_{self}^a + \mathbf{H}_{image}^a) \cdot (\mathbf{n} \times \mathbf{E}^a) dS = D_{self} + D_{image}, \quad (4.17)$$

then

$$D_{self} = -j\omega\epsilon \int_{S_a} \int_{S_a} \phi(\rho)(G_{xx} + G_{zz})\phi(\rho') dS dS' = -j\omega\epsilon C_{11}, \quad (4.18)$$

where C_{mn} is calculated in Eq. (3.40). For small kd Γ D_{self} has a series expansion in the form

$$Im D_{self} = \frac{\pi^2 d^2}{6Z_0} \left(\frac{1}{\alpha} - \frac{3}{5}\alpha + \dots \right), \quad (4.19)$$

$$Re D_{self} = -\frac{4\pi d^2}{27Z_0} \alpha^2 \left(1 - \frac{3}{25}\alpha^2 + \dots \right), \quad (4.20)$$

with $\alpha = kd$. In the low frequency range Γ the imaginary part of D_{self} is dominant which results in $Z(k) \sim jk$. Thus Γ when we compare D_{self} with the contribution from the image sources Γ D_{image} Γ we compare the imaginary part at the low frequency.

For $D_{image}\Gamma$ we use the small hole approximation so that the image-source is replaced by the x -directed magnetic dipole moment M . The dipole moment may be calculated using a general relation

$$\int_{S_a} \mathbf{J}_m dS = - \int_{S_a} \mathbf{r} \nabla \cdot \mathbf{J}_m dS = j\omega \int_{S_a} \mathbf{r} \rho_m dS = j\omega \mu \mathbf{M}, \quad (4.21)$$

which results in $j\omega \mu \mathbf{M} = \frac{4\pi d^2}{3} \mathbf{e}_x$ located at $x = 2na$, $n = 0, \pm 1, \pm 2, \dots$ and $y = 2mb$, $m = 0, \pm 1, \pm 2, \dots \Gamma$ excluding the origin.

In order to calculate the magnetic field due to all image dipoles [9] Γ it may be convenient to use the Hertzian potential of magnetic type $\Gamma \mathbf{\Pi}$. Since the magnetic dipole moment is x -directed $\Gamma \mathbf{\Pi}$ has only an x component which satisfies the wave equation

$$\nabla^2 \Pi_x + k^2 \Pi_x = -M \text{ and } H_x = k^2 \Pi_x + \frac{\partial^2 \Pi_x}{\partial x^2}. \quad (4.22)$$

For a row of dipoles located at $y = \pm 4mb \Gamma m = 0, 1, 2, \dots \Gamma$ the potential becomes

$$\Pi_1 = \frac{M}{4\pi} \sum_{m=-\infty}^{m=\infty} \frac{\exp \left[-jk \sqrt{x^2 + (y - 4mb)^2 + z^2} \right]}{\sqrt{x^2 + (y - 4mb)^2 + z^2}}. \quad (4.23)$$

For this infinite sum Γ we use Poisson's sum formula defined as

$$\sum_{n=-\infty}^{\infty} f(n\alpha) = \frac{1}{\alpha} \sum_{n=-\infty}^{\infty} F\left(\frac{2n\pi}{\alpha}\right), \quad F(\omega) = \int_{-\infty}^{\infty} f(t) e^{j\omega t} dt. \quad (4.24)$$

The required Fourier transformation is the integral of the type

$$\begin{aligned} I &= \int_{-\infty}^{\infty} e^{jqy} \frac{e^{-jk \sqrt{x^2 + (y-u)^2}}}{\sqrt{x^2 + (y-u)^2}} du \\ &= e^{jqy} \int_{-\infty}^{\infty} e^{jqz} \frac{e^{-jk \sqrt{x^2 + z^2}}}{\sqrt{x^2 + z^2}} dz \\ &= e^{jqy} \int_{-\infty}^{\infty} e^{-x(q \cosh \theta + k \sinh \theta)} d\theta \\ &= e^{jqy} \int_{-\infty}^{\infty} e^{-x \sqrt{q^2 - k^2} \cosh(\theta + \psi)} d\theta \\ &= 2e^{jqy} K_0[\sqrt{q^2 - k^2} x], \end{aligned} \quad (4.25)$$

where $K_0(x)$ is the modified Bessel function of the second kind.

Thus $\Gamma\Pi_1$ becomes

$$\Pi_1 = \frac{M}{8\pi b} \left\{ K_0[jk\sqrt{x^2 + z^2}] + 2 \sum_{m=1}^{m=\infty} \cos \frac{m\pi y}{2b} K_0[\Gamma_{0m}\sqrt{x^2 + z^2}] \right\}, \quad (4.26)$$

where $\Gamma_{0m} = [(m\pi/2b)^2 - k^2]$.

The potential arising from all the image dipoles is obtained by replacing x by $x - 2na$ in Eq. (4.26). Excluding the contribution from the dipole at the origin Γ

$$\begin{aligned} \Pi_2 &= \frac{M}{8\pi b} \sum_{n=-\infty}^{\infty} ' K_0[jk\sqrt{(x - 2na)^2 + z^2}] \\ &+ \frac{M}{4\pi b} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \cos \frac{m\pi y}{2b} K_0[\Gamma_{0m}\sqrt{(x - 2na)^2 + z^2}] \\ &+ \frac{M}{2\pi} \sum_{m=1}^{\infty} \frac{\exp[-jk\sqrt{x^2 + (y - 4mb)^2 + z^2}]}{\sqrt{x^2 + (y - 4mb)^2 + z^2}}. \end{aligned} \quad (4.27)$$

The first term is the contribution from the dipoles on the x -axis excluding the origin Γ the second term is from the dipoles not on the axis Γ and the third term is from the dipoles on the y -axis excluding the origin.

Since the evaluation of H_x involves derivatives with respect to x only Γ we may place y and z equal to zero which results in

$$\begin{aligned} \Pi_3 &= \frac{M}{8\pi b} \sum_{n=-\infty}^{\infty} ' K_0[jk|x - 2na|] + \frac{M}{4\pi b} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} K_0[\Gamma_{0m}|x - 2na|] \\ &+ \frac{M}{2\pi} \sum_{m=1}^{\infty} \frac{\exp[-jk\sqrt{x^2 + (4mb)^2}]}{\sqrt{x^2 + (4mb)^2}}. \end{aligned} \quad (4.28)$$

Assuming a low frequency in the range where Γ_{0m} is real Γ we may neglect the second term as $K_0(x)$ decreases exponentially when x is real. But the first series converges very slowly so that we transform the series into the form suitable for using

Poisson's sum formula Γ

$$\frac{M}{8\pi b} \sum_{n=-\infty}^{\infty} K_0[jk|x - 2na|] - \frac{M}{8\pi b} K_0[jk|x|]. \quad (4.29)$$

A necessary integral is¹

$$\int_{-\infty}^{\infty} e^{jq_u} K_0[jk\sqrt{(x-u)^2 + z^2}] du = \frac{\pi}{\sqrt{q^2 - k^2}} e^{jq_x - z\sqrt{q^2 - k^2}} \quad (4.30)$$

from which we obtain

$$\frac{M}{8\pi b} \sum_{n=-\infty}^{\infty} K_0[jk|x - 2na|] = \frac{M}{16ab} \frac{e^{j\frac{n\pi}{a}x}}{\Gamma_{0n}}, \quad (4.31)$$

where $\Gamma_{0n} = \sqrt{(n\pi/a)^2 - k^2}$.

The final expression for Π_x becomes

$$\Pi_x = \frac{M}{16ab} \sum_{n=-\infty}^{\infty} \frac{e^{j\frac{n\pi}{a}x}}{\Gamma_{0n}} - \frac{M}{8\pi b} K_0[jk|x|] + \frac{M}{2\pi} \sum_{m=1}^{\infty} \frac{\exp[-jk\sqrt{x^2 + (4mb)^2}]}{\sqrt{x^2 + (4mb)^2}}. \quad (4.32)$$

For the field $\Gamma H_x \Gamma$ we need $\partial^2 \Pi_x / \partial x^2$ which is given by

$$\begin{aligned} \frac{\partial^2 \Pi_x}{\partial x^2} &= -\frac{M}{16ab} \sum_{n=-\infty}^{\infty} \left(\frac{n\pi}{a}\right)^2 \frac{e^{j\frac{n\pi}{a}x}}{\Gamma_{0n}} + \frac{Mk^2}{8\pi b} \left[K_0(jkx) + \frac{K_1(jkx)}{jkx} \right] \\ &+ \frac{M}{2\pi} \sum_{m=1}^{\infty} \frac{e^{-jkr_m}}{r_m} \left[\frac{jkx}{r_m^2} + \frac{2x}{r_m^3} - \frac{k^2x}{r_m} + \frac{jkx}{r_m} - \left(jk + \frac{1}{r_m} \right) \left(\frac{1}{r_m} - \frac{x^2}{r_m^3} \right) \right], \end{aligned}$$

where $r_m = \sqrt{x^2 + (4mb)^2}$.

Thus ΓH_x at the origin becomes

$$\begin{aligned} H_x &= k^2 \Pi_x + \frac{\partial^2 \Pi_x}{\partial x^2} \\ &= -\frac{M}{16ab} \sum_{n=-\infty}^{\infty} \Gamma_{0n} e^{j\frac{n\pi}{a}x} + \frac{Mk^2}{8\pi b} \frac{K_1(jkx)}{jkx} \\ &+ \frac{M}{2\pi} \left[k^2 \sum_1^{\infty} \frac{e^{-jk4mb}}{4mb} - \sum_1^{\infty} \frac{e^{-jk4mb}}{4mb} \left(\frac{jk}{4mb} + \frac{1}{(4mb)^2} \right) \right]. \quad (4.33) \end{aligned}$$

¹See reference [13], p. 736.

Necessary formulas in evaluating the various geometric series in Eq. (4.33) are given in Table 4.1.

If Γ_{0n} is approximately taken to be $n\pi/a - k^2a/2\pi n\Gamma$ the first series has the dominant part

$$-\frac{M}{8ab} \sum_{n=1}^{\infty} e^{j\frac{n\pi}{a}x} \left(\frac{n\pi}{a} - \frac{ak^2}{2\pi n} \right) - j \frac{M}{16ab} k$$

which is readily summed to give

$$\frac{M}{8\pi b} \left[j \left(\frac{\pi k^2}{4} - \frac{\pi k}{2a} \right) - \frac{k^2}{2} \ln 2 \sin \frac{\pi x}{2a} + \frac{1}{x^2} \right],$$

plus a correction part

$$-\frac{M}{8ab} \sum_{n=1}^{\infty} \left(\Gamma_{0n} - \frac{n\pi}{a} + \frac{ak^2}{2\pi n} \right).$$

Thus the first series becomes

$$\frac{M}{8\pi b} \left[j \left(\frac{k^2}{4} - \frac{\pi k}{2a} \right) - \frac{k^2}{2} \ln 2 \sin \frac{\pi x}{2a} + \frac{1}{x^2} - \frac{\pi}{a} \sum_{n=1}^{\infty} (\dots) \right]. \quad (4.34)$$

For small $x\Gamma$ the second term in H_x becomes

$$\frac{M}{8\pi b} \left[\frac{k^2}{4} (2\gamma - 1) + \frac{k^2}{2} \ln \left(\frac{jkx}{2} \right) - \frac{1}{x^2} \right], \quad (4.35)$$

where $\gamma = 0.577\dots$ is Euler's constant. We notice that the singularity in x vanishes as x goes to zero.

The third series can be summed to give

$$\frac{M}{8\pi b} \left[\frac{k^2}{2} (\ln 4kb - 2 \ln 2 \sin 2kb) - \frac{k^2}{4} - \frac{b^2 k^4}{6} + j \left(\frac{4bk^3}{3} - \frac{\pi k^2}{4} \right) \right]. \quad (4.36)$$

Finally ΓH_x at the origin is given as

$$\begin{aligned} Re H_x &= \frac{M}{8\pi b} \left[(\ln 4kb - 2 \ln 2 \sin 2kb + \gamma - 1) \frac{k^2}{2} - \frac{b^2}{6} k^4 - \frac{\pi}{a} \sum_{n=1}^{\infty} (\dots) \right], \\ Im H_x &= -\frac{M}{8\pi b} \left(\frac{\pi}{2a} k - \frac{4b}{3} k^3 \right), \end{aligned}$$

$\sum_1^\infty e^{jn x}$	$\frac{e^{jx}}{1-e^{jx}} = -\frac{1}{2} + \frac{j}{2} \cot \frac{x}{2},$	$0 < x < \pi$
$\sum_1^\infty n e^{jn x}$	$-\frac{1}{4} \csc^2 \frac{x}{2} = -\frac{1}{x^2} \left(1 + \frac{x^2}{3} + \frac{87x^4}{2880} + \dots\right),$	$0 < x < \pi$
$\sum_1^\infty \frac{e^{jn x}}{n}$	$-\ln(1 - e^{jx}) = -\ln 2 \sin \frac{x}{2} + j \frac{\pi-x}{2},$	$0 < x < 2\pi$
$\sum_1^\infty \frac{e^{jn x}}{n^2}$	$\frac{\pi^2}{6} - \frac{x}{4}(2\pi - x) - j \left(x \ln x - x - \frac{x^3}{72} \dots\right),$	$0 < x < 2\pi$
$\sum_1^\infty \frac{e^{jn x}}{n^3}$	$j \left(\frac{\pi^2 x}{6} - \frac{\pi x^2}{4} + \frac{x^3}{12}\right) + \left(\frac{x^2}{2} \ln x - \frac{3x^2}{4} - \frac{x^4}{288} - \dots\right) + \sum_{n=1}^\infty \frac{1}{n^3},$	$0 < x < 2\pi$
$\sum_1^\infty \frac{1}{n^2}$	$\frac{\pi^2}{6}$	
$\sum_1^\infty \frac{1}{n^3}$	1.202056903	

Table 4.1: Geometric Series

which is valid for low frequencies.

With this field Γ we obtain

$$Im D_{image} \simeq -\frac{\pi^2 d^2}{9Z_0} \left(\frac{d}{b}\right) \alpha, \quad \alpha = kd. \quad (4.37)$$

Comparing this with $D_{self} \Gamma$ we see that the contribution to the impedance from image sources is negligible in the low frequency range if the hole size is small compared with the waveguide dimension Γ which is often the case in a typical accelerator beam pipe.

Thus Γ for the hole in a rectangular waveguide Γ we use the same analytic formulas obtained for the impedance of a hole in an infinite screen except that the source field appearing in the formula Γ Eq. (3.56) Γ must be evaluated in the waveguide which is shown in Eq. (4.11).

4.4 Comparison with Numerical Results

In order to verify our analytical results we compare them with the numerical results from MAFIA-T3 which is a 3-D wake potential program. As mentioned in Chapter 1 MAFIA-T3 simply calculates the wake potential of the charge distributed in space i.e. bunch potential. It assumes a bunch of charged particles in Gaussian distribution moving with velocity equal to the speed of light.

One of the geometries used in the MAFIA-T3 simulation is shown in Fig. 4.3 where we use a waveguide of width $2a = 2\text{ cm}$ height $2b = 1\text{ cm}$ the radius of a hole $d = 4\text{ mm}$ and thickness of a hole plane $t = 1\text{ mm}$. Although our method has been developed for a hole in a zero thickness plane the numerical program cannot handle zero thickness.

The corresponding bunch potential together with the Gaussian bunch shape are shown in Fig. 4.4. We observe that the wake potential has a long tail similar to a damped harmonic oscillator. Such a long range wake potential results in an impedance with narrow bandwidth at a well-defined resonant frequency. Resonance phenomena are expected because the induced field in the hole bounded by the circular conducting edge will support a standing wave. When the hole size is reduced to 1 mm wake potential is quickly damped out after the bunch traverses the hole. Such a short-range wake is shown in Fig. 4.5. Because of the short range in time it will exhibit a broadband impedance in the frequency domain.

With this wake potential we have to perform a Fourier transform in order to obtain the coupling impedance. The first step is to calculate $V(\omega)$ which is the direct Fourier transform of bunch potential from MAFIA-T3. For $d = 4\text{ mm}$ the result is

shown in Fig. 4.6.

After this step we can obtain the coupling impedance by

$$Z(\omega) = \frac{V(\omega)}{I(\omega)}, \quad I(\omega) = \exp \left[-\frac{1}{2}(\omega\sigma_z/c)^2 \right], \quad (4.38)$$

where $I(\omega)$ is the Fourier transform of the Gaussian bunch with rms bunch length σ_z .

In practice $Z(\omega)$ can be computed only up to some limiting frequency because of the exponential factor in the equation. We choose the limiting frequency to be the one for which the exponential factor is five. Results for a hole of radius 4 mm are presented in Fig. 4.7 showing the resonance behavior with sharp peaks.

As a general rule three-dimensional mesh programs such as MAFIA-T3 require a large amount of CPU time and a considerable memory size. In order to reduce the number of meshes we take advantage of the symmetry in geometry. For example instead of using full geometry as shown in Fig. 4.3 and running the program once with the boundary condition

$$\text{tangential electric field } \mathbf{E}_{\parallel} = 0 \text{ on the guide walls,}$$

we may use only the bottom half of the geometry with two separate boundary conditions $\mathbf{E}_{\parallel} = 0$ and $\mathbf{H}_{\parallel} = 0$ on the plane of the hole (symmetry plane). By doing this we can save both the number of meshes and the CPU time.

Three different results one using full geometry and the other two using half geometry with $\mathbf{E}_{\parallel} = 0$ or $\mathbf{H}_{\parallel} = 0$ are shown in Fig. 4.8. We notice that the impedance from the $\mathbf{E}_{\parallel} = 0$ boundary condition is completely negligible. In fact if the thickness becomes infinitesimal its impedance should be zero. Thus by utilizing the symmetry configuration we only use half geometry with boundary condition $\mathbf{H}_{\parallel} = 0$ and divide the result by a factor of two in order to achieve the same result as the one from full

geometry. All results from MAFIA-T3 calculations shown in the later figures were obtained by this method.

We compare the coupling impedance from the variational method and from MAFIA-T3 simulations for the holes with radius 1 mm, 2 mm, 4 mm. The result for the hole with radius 1 mm is shown in Fig. 4.9. Since the ratio $d/b = 0.2$ is small, our variational result based on the assumption that the interaction between the hole and waveguide is small is expected to be in good agreement with the numerical result which includes the effect of waveguide structure. From the MAFIA-T3 results we find that the resonance occurs at the frequency $kd = 1.8$. The variational result shows the resonance at $kd = 1.35$. Although the predictions of resonant frequency from the two methods do not agree, results indicate that the resonance behavior is a property of the hole because the frequency of the dominant propagating mode is 16 GHz for the TM_{11} mode which is far below the resonant frequency. We also observe that the variational result at the low frequency range is approximately a factor two larger than the numerical one. This may be explained as the thickness effect. Gluckstern [11] has shown that the coupling impedance of a hole in an infinite screen with finite thickness is reduced by a certain factor which depends on the ratio t/d compared to one in a zero-thickness screen. His result shows that the reduction factor for $t/d = 1$ is 0.567. If we include this factor in the variational result we have a better agreement with the numerical one as shown in Fig. 4.10. In this comparison we should note that if the hole size is small compared with the waveguide dimension, the characteristics of coupling impedance can be explained by the consideration of a hole only.

For the hole with radius 2 mm, the numerical result presented in Fig. 4.11 exhibits noisy peaks which we believe indicate the effects of the waveguide. However, its well-

defined envelope shows the behavior of a broadband resonator with the resonance at $kd = 1.8$ the same as the impedance for radius 1 mm. Except for the location of the resonant frequency the result from the variational method shows good agreement in magnitude. The reduction factor of 0.61 due to the thickness effect for $t/d = 0.5$ is included in the variational result.

An interesting behavior is observed from the numerical results for the hole with radius 4mm. Since the ratio of a hole radius and waveguide half width is comparable the waveguide effect may not be negligible any more. The result in Fig. 4.12 shows a strong interaction between hole and waveguide at the frequency of 16 GHz. It corresponds to a dominant propagating mode of TM_{11} . TE_{mn} modes are not important because they do not contribute to the longitudinal coupling impedance. The reduction factor 0.70 for $t/d = 0.25$ is taken into account in the variational result.

We have shown that the results from two different methods are in good agreement when the hole is small compared with the waveguide dimension. It indicates that for a small hole the effect from waveguide structure is minor because our variational method does not take into account such an effect. We also find that the thickness effect is not negligible unless $t/d \ll 1$.

Chapter 5

Summary and Conclusion

In this work we have derived analytic formulas using a variational method for the coupling impedance of a hole in an infinite screen and in a rectangular waveguide. The waveguide is considered as a model geometry resembling a real accelerator beam pipe. Utilizing Bethe's solution for the tangential electric field as our assumed field in the hole we have shown that the coupling impedance can be expressed as a sum of finite functional series. The functions appearing in the formula are all well tabulated [1] enabling us to evaluate the numerical values readily.

When we compare our variational formula for the impedance with a well-known low frequency formula we find that the two results agree.

Finally we have compared our variational results with the impedance obtained by the Fourier transform of the wake potential data from the program MAFIA-T3. We have shown a good qualitative agreement between two different methods in a wide frequency range.

Although one can in principle use MAFIA-T3 to calculate the impedance for a realistic accelerator beam pipe with holes it will be very difficult to interpret or to understand the numerical data. In particular when we try to parameterize the

impedance with a model for example the broadband resonator model we may not know whether the exact shape of the beam pipe is important or not. If important we must include a beam pipe dimension as a parameter in order to fit the numerical data. But we simply cannot answer such questions from numerical results alone.

From the analytical treatment presented in this work we have shown that important parameters such as the resonant frequency and the bandwidth of resonance peak can be derived as functions of the dimensionless quantity kd where k is the free-space wave number and d is the radius of a hole. Since these two parameters together with the slope of impedance at low frequency are enough to describe a resonator our findings are very useful in understanding a complicated behavior of impedance obtained by numerical programs.

In conclusion we have raised the treatment of the hole-coupling problem from the analysis valid in the low frequency range to one valid in a wide range of frequencies. By doing so we have succeeded in enlarging our understanding of the hole-coupling problem.

As a further investigation we may continue to develop a semi-analytical method for the estimate of the coupling impedance of an arbitrarily shaped aperture in a realistic beam pipe. This effort may have dual purposes. First it can be used to verify the purely analytical result especially the one from an approximate method such as a variational method which we considered in this work. Secondly it may enable us to calculate the impedance without a severe requirement on computer time and memory which often limits the usefulness of the purely numerical method such as the computer code MAFIA-T3.
